

# Learn Python The Hard Way, 3rd Edition

Welcome to the 3rd Edition of Learn Python the hard way. You can visit the companion site to the book at <http://learnpythonthehardway.org/> where you can purchase digital downloads and paper versions of the book. The free HTML version of the book is available at <http://learnpythonthehardway.org/book/>.

## Table Of Contents

- [The Hard Way Is Easier](#)
- [Exercise 0: The Setup](#)
- [Exercise 1: A Good First Program](#)
- [Exercise 2: Comments And Pound Characters](#)
- [Exercise 3: Numbers And Math](#)
- [Exercise 4: Variables And Names](#)
- [Exercise 5: More Variables And Printing](#)
- [Exercise 6: Strings And Text](#)
- [Exercise 7: More Printing](#)
- [Exercise 8: Printing, Printing](#)
- [Exercise 9: Printing, Printing, Printing](#)
- [Exercise 10: What Was That?](#)
- [Exercise 11: Asking Questions](#)
- [Exercise 12: Prompting People](#)
- [Exercise 13: Parameters, Unpacking, Variables](#)
- [Exercise 14: Prompting And Passing](#)
- [Exercise 15: Reading Files](#)
- [Exercise 16: Reading And Writing Files](#)
- [Exercise 17: More Files](#)
- [Exercise 18: Names, Variables, Code, Functions](#)
- [Exercise 19: Functions And Variables](#)
- [Exercise 20: Functions And Files](#)
- [Exercise 21: Functions Can Return Something](#)
- [Exercise 22: What Do You Know So Far?](#)
- [Exercise 23: Read Some Code](#)
- [Exercise 24: More Practice](#)
- [Exercise 25: Even More Practice](#)
- [Exercise 26: Congratulations, Take A Test!](#)
- [Exercise 27: Memorizing Logic](#)
- [Exercise 28: Boolean Practice](#)
- [Exercise 29: What If](#)

- [Exercise 30: Else And If](#)
- [Exercise 31: Making Decisions](#)
- [Exercise 32: Loops And Lists](#)
- [Exercise 33: While Loops](#)
- [Exercise 34: Accessing Elements Of Lists](#)
- [Exercise 35: Branches and Functions](#)
- [Exercise 36: Designing and Debugging](#)
- [Exercise 37: Symbol Review](#)
- [Exercise 38: Doing Things To Lists](#)
- [Exercise 39: Dictionaries, Oh Lovely Dictionaries](#)
- [Exercise 40: Modules, Classes, And Objects](#)
- [Exercise 41: Learning To Speak Object Oriented](#)
- [Exercise 42: Is-A, Has-A, Objects, and Classes](#)
- [Exercise 43: Gothons From Planet Percal #25](#)
- [Exercise 44: Inheritance Vs. Composition](#)
- [Exercise 45: You Make A Game](#)
- [Exercise 46: A Project Skeleton](#)
- [Exercise 47: Automated Testing](#)
- [Exercise 48: Advanced User Input](#)
- [Exercise 49: Making Sentences](#)
- [Exercise 50: Your First Website](#)
- [Exercise 51: Getting Input From A Browser](#)
- [Exercise 52: The Start Of Your Web Game](#)
- [Advice From An Old Programmer](#)
- [Next Steps](#)

## Common Student Questions

How long does this course take?

You should take as long as it takes to get through it, but focus on doing work every day. Some people take about 3 months, others 6 months, and some only a week. I can do it in about 4 hours or less if I hurry and don't do the extra credits.

What kind of computer do I need?

You can do it on most any computer. It works on Windows, Mac OSX, and Linux with instructions for all three in the first exercise.

# The Hard Way Is Easier

This simple book is meant to get you started in programming. The title says it's the hard way to learn to write code; but it's actually not. It's only the "hard" way because it's the way people *used* to teach things using *instruction*. This book instructs you in Python by slowly building and establishing skills through techniques like practice and memorization, then applying them to increasingly difficult problems.

With the help of this book, you will do the incredibly simple things that all programmers need to do to learn a language:

1. Go through each exercise.
2. Type in each sample *exactly*.
3. Make it run.

That's it. This will be *very* difficult at first, but stick with it. If you go through this book, and do each exercise for one or two hours a night, you will have a good foundation for moving onto another book. You might not really learn "programming" from this book, but you will learn the foundation skills you need to start learning the language.

This book's job is to teach you the three most essential skills that a beginning programmer needs to know: Reading and Writing, Attention to Detail, Spotting Differences.

## Reading and Writing

It seems stupidly obvious, but, if you have a problem typing, you will have a problem learning to code. Especially if you have a problem typing the fairly odd characters in source code. Without this simple skill you will be unable to learn even the most basic things about how software works.

Typing the code samples and getting them to run will help you learn the names of the symbols, get familiar with typing them, and get you reading the language.

## Attention to Detail

The one skill that separates bad programmers from good programmers is attention to detail. In fact, it's what separates the good from the bad in any profession. Without paying attention to the tiniest details of your work, you will miss key elements of what you create. In programming, this is how you end up with bugs and difficult-to-use systems.

By going through this book, and copying each example *exactly*, you will be training your brain to focus on the details of what you are doing, as you are doing it.

# Spotting Differences

A very important skill -- that most programmers develop over time -- is the ability to visually notice differences between things. An experienced programmer can take two pieces of code that are slightly different and immediately start pointing out the differences. Programmers have invented tools to make this even easier, but we won't be using any of these. You first have to train your brain the hard way, then you can use the tools.

While you do these exercises, typing each one in, you will be making mistakes. It's inevitable; even seasoned programmers would make a few. Your job is to compare what you have written to what's required, and fix all the differences. By doing so, you will train yourself to notice mistakes, bugs, and other problems.

# Do Not Copy-Paste

You must *type* each of these exercises in, manually. If you copy and paste, you might as well just not even do them. The point of these exercises is to train your hands, your brain, and your mind in how to read, write, and see code. If you copy-paste, you are cheating yourself out of the effectiveness of the lessons.

# A Note On Practice And Persistence

While you are studying programming, I'm studying how to play guitar. I practice it every day for at least 2 hours a day. I play scales, chords, and arpeggios for an hour at least and then learn music theory, ear training, songs and anything else I can. Some days I study guitar and music for 8 hours because I feel like it and it's fun. To me repetitive practice is natural and just how to learn something. I know that to get good at anything you have to practice every day, even if I suck that day (which is often) or it's difficult. Keep trying and eventually it'll be easier and fun.

As you study this book, and continue with programming, remember that anything worth doing is difficult at first. Maybe you are the kind of person who is afraid of failure so you give up at the first sign of difficulty. Maybe you never learned self-discipline so you can't do anything that's "boring". Maybe you were told that you are "gifted" so you never attempt anything that might make you seem stupid or not a prodigy. Maybe you are competitive and unfairly compare yourself to someone like me who's been programming for 20+ years.

Whatever your reason for wanting to quit, *keep at it*. Force yourself. If you run into an Extra Credit you can't do, or a lesson you just do not understand, then skip it and come back to it later. Just keep going because with programming there's this very odd thing that happens.

At first, you will not understand anything. It'll be weird, just like with learning any human language. You will struggle with words, and not know what symbols are what, and it'll all be very confusing. Then one day *BANG* your brain will snap and you will suddenly "get it". If you keep doing the exercises and keep trying to understand them, you will get it. You might not be a master coder, but you will at least understand how programming works.

If you give up, you won't ever reach this point. You will hit the first confusing thing (which is everything at first) and then stop. If you keep trying, keep typing it in, trying to understand it and reading about it, you will eventually get it.

But, if you go through this whole book, and you still do not understand how to code, at least you gave it a shot. You can say you tried your best and a little more and it didn't work out, but at least you tried. You can be proud of that.

# A Warning For The Smarties

Sometimes people who already know a programming language will read this book and feel I'm insulting them. There is nothing in this book that is intended to be interpreted as condescending, insulting, or belittling. I simply know more about programming than my *intended* readers. If you think you are smarter than me then you will feel talked down to and there's nothing I can do about that because you are not my *intended* reader.

If you are reading this book and flipping out at every third sentence because you feel I'm insulting your intelligence, then I have three points of advice for you:

1. Stop reading my book. I didn't write it for you. I wrote it for people who don't already know everything.
2. Empty before you fill. You will have a hard time learning from someone with more knowledge if you already know everything.
3. Go learn Lisp. I hear people who know everything really like Lisp.

For everyone else who's here to learn, just read everything as if I'm smiling and I have a mischievous little twinkle in my eye.

## License

This book is Copyright (C) 2010 by Zed A. Shaw.

## Special Thanks

I'd like to thank a few people who helped with this edition of the book. First is my editor at *Pretty Girl Editing Services* who helped me edit the book and is just lovely all by herself. Then there's *Greg Newman*, who did the cover jacket and artwork, plus reviewed copies of the book. His artwork made the book look like a real book, and didn't mind that I totally forgot to give him credit in the first edition. I'd also like to thank *Brian Shumate* for doing the website landing page and other site design help, which I need a lot of help on.

Finally, I'd like to thank the hundreds of thousands of people who read the first edition and especially the ones who submitted bug reports and comments to improve the book. It really made this edition solid and I couldn't have done it without all of you. Thank you.

# Exercise 0: The Setup

This exercise has no code. It is simply the exercise you complete to get your computer setup to run Python. You should follow these instructions as exactly as possible. For example, Mac OSX computers already have Python 2, so do not install Python 3 (or any Python).

## Warning

If you do not know how to use PowerShell on Windows or the Terminal on OSX or "bash" on Linux then you need to go learn that first. I have a quick crash course at <http://cli.learncodethehardway.org/> which is free and will teach you the basics of PowerShell and Terminal quickly. Go through that then come back here.

## Mac OSX

To complete this exercise, complete the following tasks:

1. Go to <http://www.barebones.com/products/textwrangler/> with your browser, get the TextWrangler text editor, and install it.
2. Put TextWrangler (your editor) in your Dock so you can reach it easily.
3. Find your "Terminal" program. Search for it. You will find it.
4. Put your Terminal in your Dock as well.
5. Run your Terminal program. It won't look like much.
6. In your Terminal program, run `python`. You run things in Terminal by just typing their name and hitting RETURN.
7. Hit CTRL-D (^D) and get out of python.
8. You should be back at a prompt similar to what you had before you typed `python`. If not find out why.
9. Learn how to make a directory in the Terminal. Search online for help.
10. Learn how to change into a directory in the Terminal. Again search online.
11. Use your editor to create a file in this directory. You will make the file, "Save" or "Save As...", and pick this directory.
12. Go back to Terminal using just the keyboard to switch windows. Look it up if you can't figure it out.
13. Back in Terminal, see if you can list the directory to see your newly created file. Search online for how to list a directory.

## OSX: What You Should See

Here's me doing the above on my computer in Terminal. Your computer would be different, so see if you can figure out all the differences between what I did and what you should do.

```
Last login: Sat Apr 24 00:56:54 on ttys001
~ $ python
Python 2.5.1 (r251:54863, Feb  6 2009, 19:02:12)
[GCC 4.0.1 (Apple Inc. build 5465)] on darwin
Type "help", "copyright", "credits" or "license" for more information.
>>> ^D
~ $ mkdir mystuff
~ $ cd mystuff
mystuff $ ls
# ... Use TextWrangler here to edit test.txt....
mystuff $ ls
test.txt
mystuff $
```

# Windows

## Note

Contributed by zhmark.

1. Go to <http://notepad-plus-plus.org/> with your browser, get the Notepad++ text editor, and install it. You do not need to be administrator to do this.
2. Make sure you can get to Notepad++ easily by putting it on your desktop and/or in Quick Launch. Both options are available during setup.
3. Run "powershell" from the start menu. Search for it and you can just hit enter to run it.
4. Make a shortcut to it on your desktop and/or Quick Launch for your convenience.
5. Run your Terminal program. It won't look like much.
6. In your Terminal program, run `python`. You run things in Terminal by just typing their name and hitting RETURN.
  1. If you run `python` and it's not there (`python is not recognized..`). Install it from <http://python.org/download>
  2. *Make sure you install Python 2 not Python 3.*
  3. You may be better off with ActiveState Python especially when you miss Administrative rights
  4. If after you install it `python` still isn't recognized then in powershell enter this:

```
[Environment]::SetEnvironmentVariable("Path", "$env:Path;C:\Python27",
"User")
```

5. Close powershell and then start it again to make sure python now runs. If it doesn't restart may be required.
7. Hit CTRL-Z (^Z), Enter and get out of python.
8. You should be back at a prompt similar to what you had before you typed python. If not find out why.
9. Learn how to make a directory in the Terminal. Search online for help.
10. Learn how to change into a directory in the Terminal. Again search online.
11. Use your editor to create a file in this directory. Make the file, "Save" or "Save As...", and pick this directory.
12. Go back to Terminal using just the keyboard to switch windows. Look it up if you can't figure it out.
13. Back in Terminal, see if you can list the directory to see your newly created file. Search online for how to list a directory.

### Warning

If you missed it, sometimes you install Python on Windows and it doesn't configure the path correctly. Make sure you enter `[Environment]::SetEnvironmentVariable("Path", "$env:Path;C:\Python27", "User")` in powershell to configure it correctly. You also have to either restart powershell or your whole computer to get it to really be fixed.

## Windows: What You Should See

```
> python
ActivePython 2.6.5.12 (ActiveState Software Inc.) based on
Python 2.6.5 (r265:79063, Mar 20 2010, 14:22:52) [MSC v.1500 32 bit (Intel)] on win32
Type "help", "copyright", "credits" or "license" for more information.
>>> ^Z

> mkdir mystuff

> cd mystuff

... Here you would use Notepad++ to make test.txt in mystuff ...

>
<bunch of unimportant errors if you installed it as non-admin - ignore them - hit
Enter>

Volume in drive C is
Volume Serial Number is 085C-7E02

Directory of C:\Documents and Settings\you\mystuff

04.05.2010  23:32    <DIR>          .
04.05.2010  23:32    <DIR>          ..
04.05.2010  23:32                6 test.txt
                1 File(s)                6 bytes
                2 Dir(s)  14 804 623 360 bytes free
```

>

You will probably see a very different prompt, Python information, and other stuff but this is the general idea. If your system is different let us know at <http://learnpythonthehardway.org> and we'll fix it.

# Linux

Linux is a varied operating system with a bunch of different ways to install software. I'm assuming if you are running Linux then you know how to install packages so here are your instructions:

1. Use your Linux package manager and install the `gedit` text editor.
2. Make sure you can get to `gedit` easily by putting it in your window manager's menu.
  1. Run `gedit` so we can fix some stupid defaults it has.
  2. Open `Preferences` select the `Editor` tab.
  3. Change `Tab width:` to 4.
  4. Select (make sure a check mark is in) `Insert spaces instead of tabs`.
  5. Turn on "Automatic indentation" as well.
  6. Open the `View` tab turn on "Display line numbers".
3. Find your "Terminal" program. It could be called `GNOME Terminal`, `Konsole`, or `xterm`.
4. Put your Terminal in your Dock as well.
5. Run your Terminal program. It won't look like much.
6. In your Terminal program, run `python`. You run things in Terminal by just typing their name and hitting RETURN.
  1. If you run `python` and it's not there, install it. *Make sure you install Python 2 not Python 3.*
7. Hit CTRL-D (^D) and get out of `python`.
8. You should be back at a prompt similar to what you had before you typed `python`. If not find out why.
9. Learn how to make a directory in the Terminal. Search online for help.
10. Learn how to change into a directory in the Terminal. Again search online.
11. Use your editor to create a file in this directory. Typically you will make the file, "Save" or "Save As..", and pick this directory.
12. Go back to Terminal using just the keyboard to switch windows. Look it up if you can't figure it out.
13. Back in Terminal see if you can list the directory to see your newly created file. Search online for how to list a directory.

## Linux: What You Should See

```
$ python
Python 2.6.5 (r265:79063, Apr 1 2010, 05:28:39)
[GCC 4.4.3 20100316 (prerelease)] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>>
$ mkdir mystuff
$ cd mystuff
# ... Use gedit here to edit test.txt ...
$ ls
test.txt
$
```

You will probably see a very different prompt, Python information, and other stuff but this is the general idea.

# Warnings For Beginners

You are done with this exercise. This exercise might be hard for you depending on your familiarity with your computer. If it is difficult, take the time to read and study and get through it, because until you can do these very basic things you will find it difficult to get much programming done.

If a programmer tells you to use `vim` or `emacs`, tell them, "No." These editors are for when you are a better programmer. All you need right now is an editor that lets you put text into a file. We will use `gedit`, `TextWrangler`, or `Notepad++` (from now on called "the text editor" or "a text editor") because it is simple and the same on all computers. Professional programmers use these text editors so it's good enough for you starting out.

A programmer may try to get you to install Python 3 and learn that. You should tell them, "When all of the python code on your computer is Python 3, then I'll try to learn it." That should keep them busy for about 10 years.

A programmer will eventually tell you to use Mac OSX or Linux. If the programmer likes fonts and typography, they'll tell you to get a Mac OSX computer. If they like control and have a huge beard, they'll tell you to install Linux. Again, use whatever computer you have right now that works. All you need is `gedit`, a Terminal, and `python`.

Finally the purpose of this setup is so you can do three things very reliably while you work on the exercises:

1. *Write* exercises using your text editor, `gedit` on Linux, `TextWrangler` on OSX, `Notepad++` on Windows.
2. *Run* the exercises you wrote.
3. *Fix* them when they are broken.
4. Repeat.

Anything else will only confuse you, so stick to the plan.

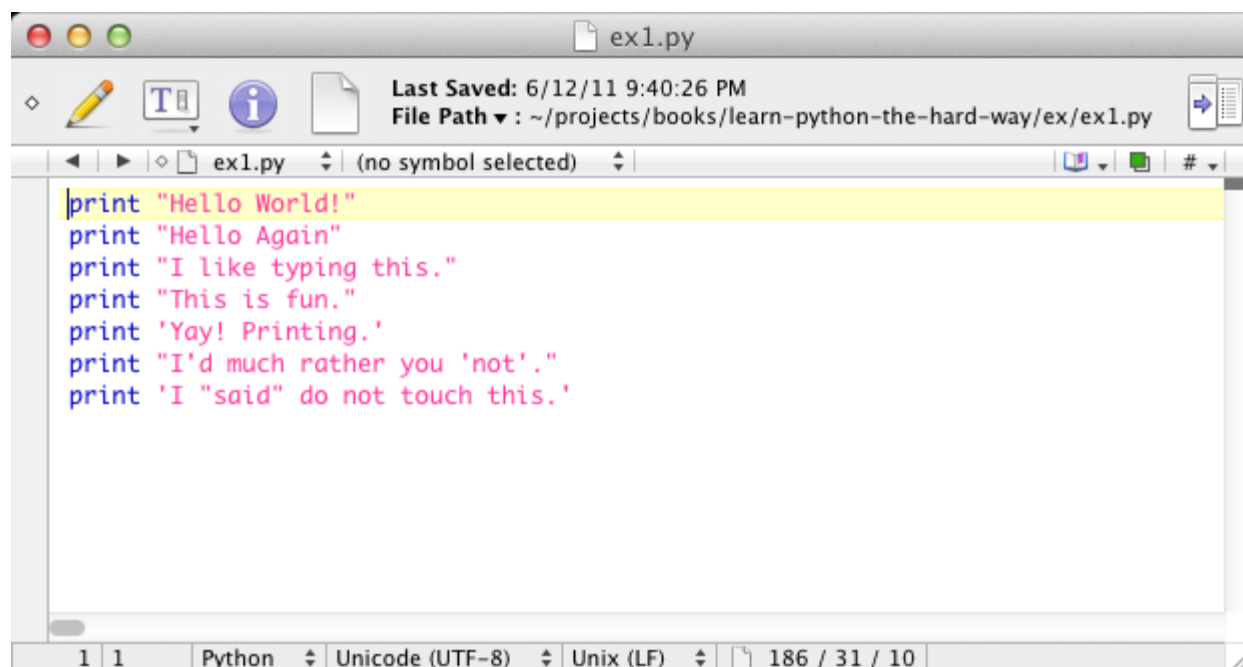

# Exercise 1: A Good First Program

Remember, you should have spent a good amount of time in Exercise 0 learning how to install a text editor, run the text editor, run the Terminal, and work with both of them. If you haven't done that then do not go on. You will not have a good time. This is the only time I'll start an exercise with a warning that you should not skip or get ahead of yourself.

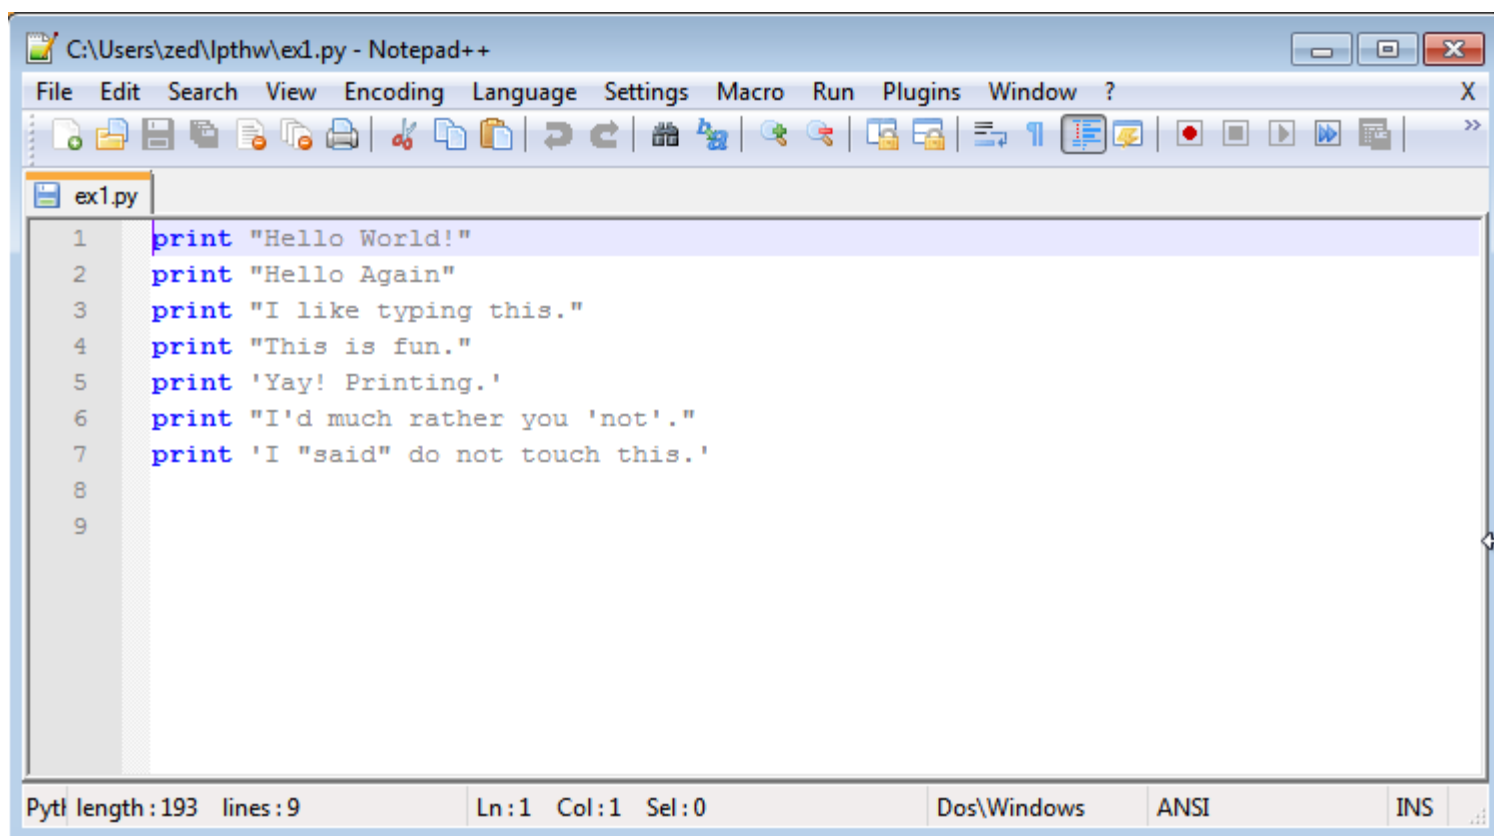

Type the following text into a single file named `ex1.py`. This is important as python works best with files ending in `.py`.

```
print "Hello World!"
print "Hello Again"
print "I like typing this."
print "This is fun."
print 'Yay! Printing.'
print "I'd much rather you 'not'."
print 'I "said" do not touch this.'
```

If you are on Mac OSX then this is what your text editor might look like if you use TextWrangler:

If you are on Windows using Notepad++ then this is what it would look like:

```

1 print "Hello World!"
2 print "Hello Again"
3 print "I like typing this."
4 print "This is fun."
5 print 'Yay! Printing.'
6 print "I'd much rather you 'not'."
7 print 'I "said" do not touch this.'
8
9

```

Pytl length: 193 lines: 9 Ln: 1 Col: 1 Sel: 0 Dos\Windows ANSI INS

Don't worry if your editor doesn't look exactly the same, the key points are:

1. Notice I did not type the line numbers on the left (1-7). Those are printed in the book so I can talk about specific lines by saying, "See line 5..." You do not type those into python scripts.
2. Notice I have the `print` at the beginning of the line and how it looks exactly the same as what I have above. Exactly means exactly, not kind of sort of the same. Every single character has to match for it to work. But, the colors are all different. Color doesn't matter, only the characters you type.

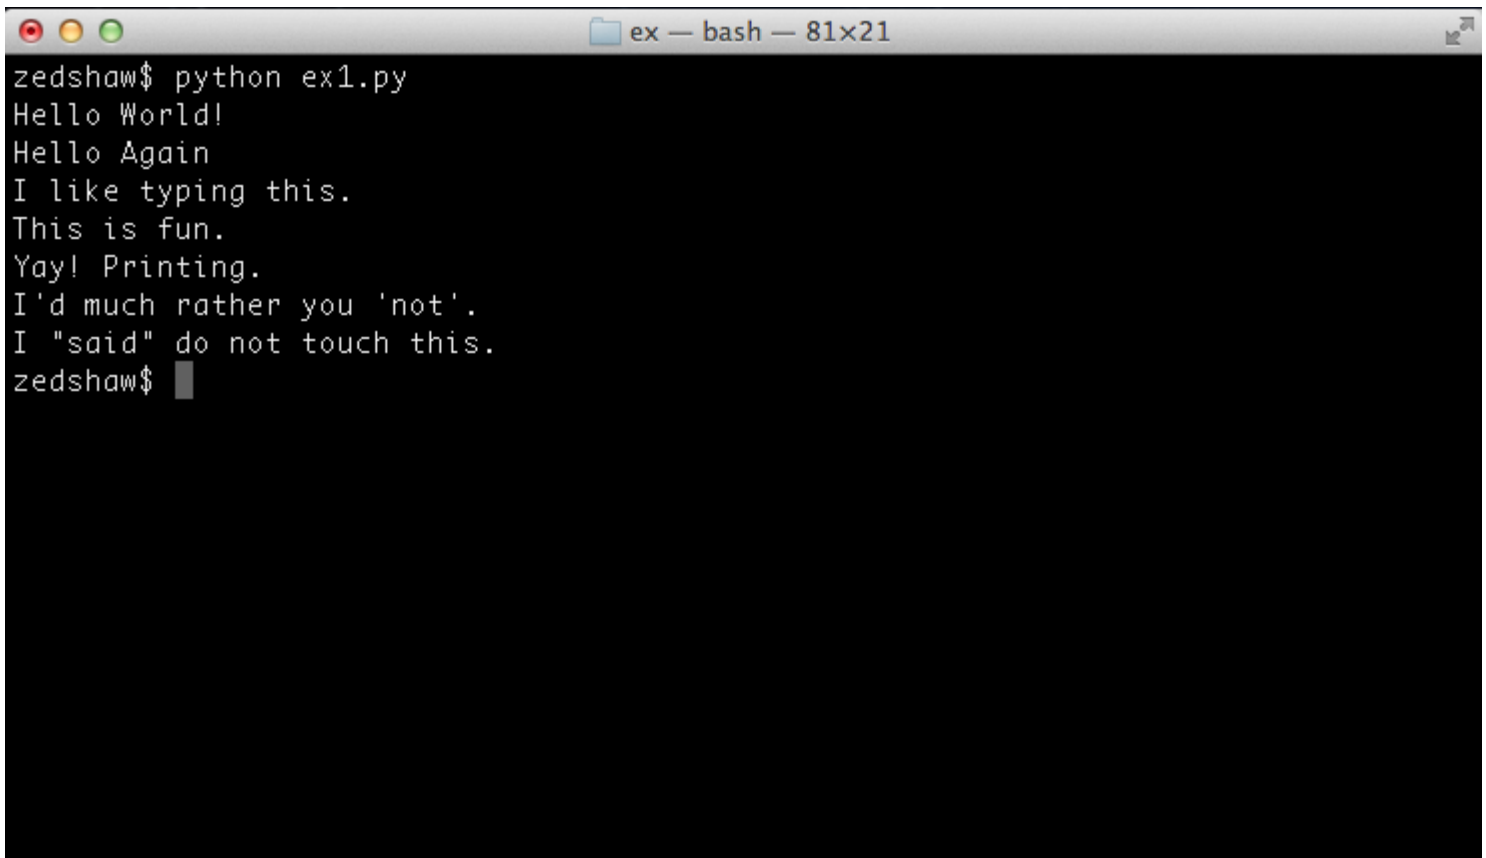

Then in Terminal *run* the file by typing:

```
python ex1.py
```

If you did it right then you should see the same output I have below. If not, you have done something wrong. No, the computer is not wrong.

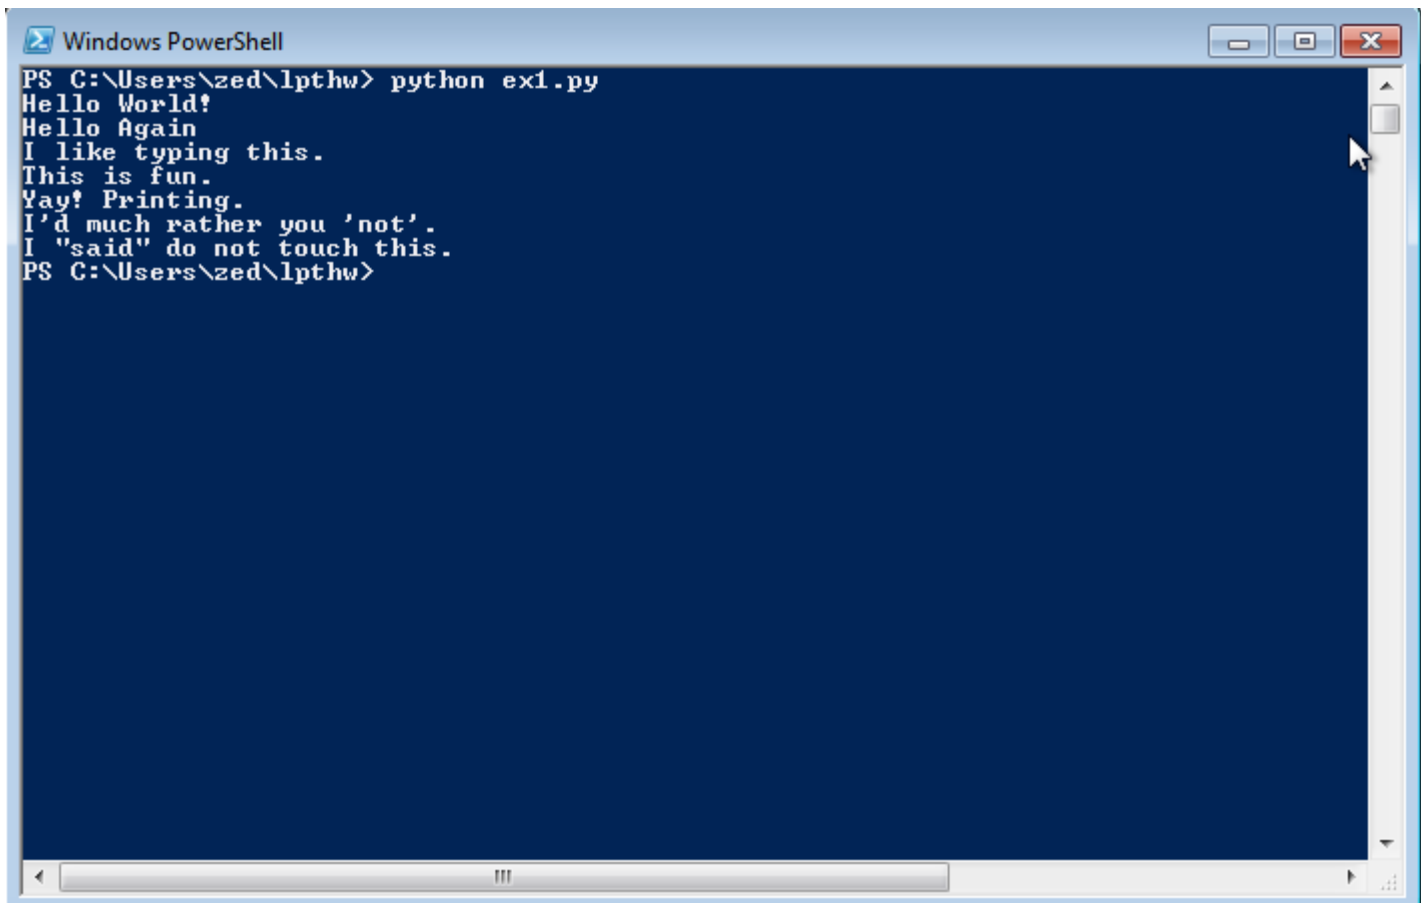

# What You Should See

On Max OSX in Terminal you should see this:

A terminal window titled "ex — bash — 81x21" with a dark background and light green text. The prompt is "zedshaw\$". The command "python ex1.py" has been executed, resulting in the following output: "Hello World!", "Hello Again", "I like typing this.", "This is fun.", "Yay! Printing.", "I'd much rather you 'not'.", and "I 'said' do not touch this.". The prompt "zedshaw\$" is followed by a cursor.

```
zedshaw$ python ex1.py
Hello World!
Hello Again
I like typing this.
This is fun.
Yay! Printing.
I'd much rather you 'not'.
I "said" do not touch this.
zedshaw$
```

On Windows in PowerShell you should see this:

A Windows PowerShell window titled "Windows PowerShell" with a dark blue background and white text. The prompt is "PS C:\Users\zed\lpthw>". The command "python ex1.py" has been executed, resulting in the same output as the Linux terminal: "Hello World!", "Hello Again", "I like typing this.", "This is fun.", "Yay! Printing.", "I'd much rather you 'not'.", and "I 'said' do not touch this.". The prompt "PS C:\Users\zed\lpthw>" is followed by a cursor.

```
PS C:\Users\zed\lpthw> python ex1.py
Hello World!
Hello Again
I like typing this.
This is fun.
Yay! Printing.
I'd much rather you 'not'.
I "said" do not touch this.
PS C:\Users\zed\lpthw>
```

You may see different names, the name of your computer or other things before the `python ex1.py` but the important part is that you type the command, and you saw the output the same as I have.

If you have an error it will look like this:

```
$ python ex/ex1.py
File "ex/ex1.py", line 3
    print "I like typing this."
          ^
SyntaxError: EOL while scanning string literal
```

It's important that you can read these since you will be making many of these mistakes. Even I make many of these mistakes. Let's look at this line-by-line.

1. Here we ran our command in the terminal to run the `ex1.py` script.
2. Python then tells us that the file `ex1.py` has an error on line 3.
3. It then prints this line for us.
4. Then it puts a `^` (caret) character to point at where the problem is. Notice the missing `"` (double-quote) character?
5. Finally, it prints out a "SyntaxError" and tells us something about what might be the error. Usually these are very cryptic, but if you copy that text into a search engine, you will find someone else who's had that error and you can probably figure out how to fix it.

### Warning

If you are from another country, and you get errors about ASCII encodings, then put this at the top of your python scripts:

```
— # -*- coding: utf-8 -*-
```

It will fix them so that you can use unicode UTF-8 in your scripts without a problem.

# Study Drills

You will also have `Study Drills`. The `Study Drills` contains things you should *try* to do. If you can't, skip it and come back later.

For this exercise, try these things:

1. Make your script print another line.
2. Make your script print only one of the lines.
3. Put a `#` (octothorpe) character at the beginning of a line. What did it do? Try to find out what this character does.

From now on, I won't explain how each exercise works unless an exercise is different.

### Note

An 'octothorpe' is also called a 'pound', 'hash', 'mesh', or any number of names. Pick the one that makes you chill out.

# Common Student Questions

These are *actual* questions by real students in the comments section of the book when it was online. You may run into some of these, so I've collected them into answers for you.

Can I use IDLE?

No, you should use Terminal on OSX and PowerShell on Windows, just like I have here. If you don't know how to use those then you can go read the Command Line Crash Course at <http://cli.learncodethehardway.org/book/>

How do you get colors in your editor?

Save your file first as a .py file, such as ex1.py. Then you'll have color when you type.

I get **SyntaxError: invalid syntax** when I run ex1.py.

You are probably trying to run python, then trying to type python again. Close your terminal, start it again, and right away type only *python ex1.py*.

I still can't get python in my PowerShell.

You may need to watch a video that tells you how to do it visually <http://www.youtube.com/watch?v=ndNIFy-5GKA>

I get **can't open file 'ex1.py': [Errno 2] No such file or directory**.

You need to be in the same directory as the file you created. Make sure you use the *cd* command to go there first. For example, if you saved your file in *lpthw/ex1.py*, then you would do *cd lpthw/* before trying to run *python ex1.py*. If you don't know what any of that means, then go through the Command Line Crash Course (CLI-CC) mentioned in question #1.

How do I get my country's language characters into my file?

Make sure you type this at the top of your file: `# -*- coding: utf-8 -*-`

My file doesn't run, I just get the prompt back with no output.

You most likely took the code in my file above literally, and thought that `print "Hello World!"` meant to literally print just "Hello World!" into the file, without the *print*. Your file has to be *exactly* like mine, and in the code above and all of the screenshots, I have `print "Hello World!"` and *print* before every line. Make sure your code is like mine and it should work.

# Exercise 2: Comments And Pound Characters

Comments are very important in your programs. They are used to tell you what something does in English, and they also are used to disable parts of your program if you need to remove them temporarily. Here's how you use comments in Python:

```
# A comment, this is so you can read your program later.
# Anything after the # is ignored by python.

print "I could have code like this." # and the comment after is ignored

# You can also use a comment to "disable" or comment out a piece of code:
# print "This won't run."

print "This will run."
```

From now on, I'm going to write code like this. It is important for you to understand that everything does not have to be literal. Your screen and program may visually look different, but what's important is the text you type into the file you're writing in your text editor. In fact, I could work with any text editor and the results would be the same.

## What You Should See

```
$ python ex2.py
I could have code like this.
This will run.
```

Again, I'm not going to show you screenshots of all the terminals possible. You should understand that the above is not a literal translation of what your output should look like visually, but that the text between the first `$ python ...` and last `$` lines will be what you focus on.

## Study Drills

1. Find out if you were right about what the `#` character does and make sure you know what it's called (octothorpe or pound character).
2. Take your `ex2.py` file and review each line going backwards. Start at the last line, and check each word in reverse against what you should have typed.

3. Did you find more mistakes? Fix them.
4. Read what you typed above out loud, including saying each character by its name. Did you find more mistakes? Fix them.

# Common Student Questions

Are you sure `#` is called the pound character?

I call it the octothorpe and that is the only name that no country uses and that works in every country. Every country thinks their way to call this one character is both the most important way to do it, and also the only way it's done. To me this is simply arrogance and really, y'all should just chill out and focus on more important things like learning to code.

If `#` is for comments, then how come `# -*- coding: utf-8 -*-` works?

Python still ignores that as code, but it's used as a kind of "hack" or workaround for problems with setting and detecting the format of a file. You also find a similar kind of comment for editor settings.

Why does the `#` in `print "Hi # there."` not get ignored?

The `#` in that code is inside a string, so it will be put into the string until the ending `"` character is hit. These pound characters are just considered characters and aren't considered comments.

How do I comment out multiple lines?

Put a `#` in front of each one.

I can't figure out how to type a `#` character on my country's keyboard?

Some countries use the Alt key and combinations of those to print characters foreign to their language. You'll have to look online in a search engine to see how to type it.

Why do I have to read code backwards?

It's a trick to make your brain not attach meaning to each part of the code, and doing that makes you process each piece exactly. This catches errors and is a handy error checking technique.

# Exercise 3: Numbers And Math

Every programming language has some kind of way of doing numbers and math. Do not worry, programmers lie frequently about being math geniuses when they really aren't. If they were math geniuses, they would be doing math, not writing ads and social network games to steal people's money.

This exercise has lots of math symbols. Let's name them right away so you know what they are called. As you type this one in, say the names. When saying them feels boring you can stop saying them. Here are the names:

- + plus
- - minus
- / slash
- \* asterisk
- % percent
- < less-than
- > greater-than
- <= less-than-equal
- >= greater-than-equal

Notice how the operations are missing? After you type in the code for this exercise, go back and figure out what each of these does and complete the table. For example, + does addition.

```
print "I will now count my chickens:"

print "Hens", 25 + 30 / 6
print "Roosters", 100 - 25 * 3 % 4

print "Now I will count the eggs:"

print 3 + 2 + 1 - 5 + 4 % 2 - 1 / 4 + 6

print "Is it true that 3 + 2 < 5 - 7?"

print 3 + 2 < 5 - 7

print "What is 3 + 2?", 3 + 2
print "What is 5 - 7?", 5 - 7

print "Oh, that's why it's False."

print "How about some more."

print "Is it greater?", 5 > -2
print "Is it greater or equal?", 5 >= -2
print "Is it less or equal?", 5 <= -2
```

# What You Should See

```
$ python ex3.py
I will now count my chickens:
Hens 30
Roosters 97
Now I will count the eggs:
7
Is it true that 3 + 2 < 5 - 7?
False
What is 3 + 2? 5
What is 5 - 7? -2
Oh, that's why it's False.
How about some more.
Is it greater? True
Is it greater or equal? True
Is it less or equal? False
```

## Study Drills

1. Above each line, use the # to write a comment to yourself explaining what the line does.
2. Remember in Exercise 0 when you started python? Start python this way again and using the above characters and what you know, use python as a calculator.
3. Find something you need to calculate and write a new `.py` file that does it.
4. Notice the math seems "wrong"? There are no fractions, only whole numbers. Find out why by researching what a "floating point" number is.
5. Rewrite `ex3.py` to use floating point numbers so it's more accurate (hint: 20.0 is floating point).

## Common Student Questions

Why is the `%` character a "modulus" and not a "percent"?

Mostly that's just how the designers chose to use that symbol. In normal writing you are correct to read it as a "percent", as in "100%" is "one hundred percent". In programming this calculation is typically done with simple division and the `/` operator. The `%` modulus is a different operation that just happens to use the `%` symbol.

How does `%` work?

Another way to say it is, "X divided by Y with J remaining." As in, "100 divided by 16 with 4 remaining." The result of `%` is the J part, or the remaining part.

What is the order of operations?

In the US we use an acronym called PEMDAS which stands for Parentheses Exponents Multiplication Division Addition Subtraction. That's the order Python follows as well.

Why does `/` (divide) round down?

It's not really rounding down, it's just dropping the fractional part after the decimal. Try doing `7.0 / 4.0` and compare it to `7 / 4` and you'll see the difference.

# Exercise 4: Variables And Names

Now you can print things with `print` and you can do math. The next step is to learn about variables. In programming a variable is nothing more than a name for something so you can use the name rather than the something as you code. Programmers use these variable names to make their code read more like English, and because they have lousy memories. If they didn't use good names for things in their software, they'd get lost when they tried to read their code again.

If you get stuck with this exercise, remember the tricks you have been taught so far of finding differences and focusing on details:

1. Write a comment above each line explaining to yourself what it does in English.
2. Read your `.py` file backwards.
3. Read your `.py` file out loud saying even the characters.

```
cars = 100
space_in_a_car = 4.0
drivers = 30
passengers = 90
cars_not_driven = cars - drivers
cars_driven = drivers
carpool_capacity = cars_driven * space_in_a_car
average_passengers_per_car = passengers / cars_driven

print "There are", cars, "cars available."
print "There are only", drivers, "drivers available."
print "There will be", cars_not_driven, "empty cars today."
print "We can transport", carpool_capacity, "people today."
print "We have", passengers, "to carpool today."
print "We need to put about", average_passengers_per_car, "in each car."
```

## Note

The `_` in `space_in_a_car` is called an underscore character. Find out how to type it if you do not already know. We use this character a lot to put an imaginary space between words in variable names.

# What You Should See

```
$ python ex4.py
There are 100 cars available.
There are only 30 drivers available.
There will be 70 empty cars today.
We can transport 120.0 people today.
We have 90 to carpool today.
We need to put about 3 in each car.
```

# Study Drills

When I wrote this program the first time I had a mistake, and *python* told me about it like this:

```
Traceback (most recent call last):
  File "ex4.py", line 8, in <module>
    average_passengers_per_car = car_pool_capacity / passenger
NameError: name 'car_pool_capacity' is not defined
```

Explain this error in your own words. Make sure you use line numbers and explain why.

Here's more extra credit:

1. I used 4.0 for `space_in_a_car`, but is that necessary? What happens if it's just 4?
2. Remember that 4.0 is a "floating point" number. Find out what that means.
3. Write comments above each of the variable assignments.
4. Make sure you know what `=` is called (equals) and that it's making names for things.
5. Remember `_` is an underscore character.
6. Try running *python* as a calculator like you did before and use variable names to do your calculations. Popular variable names are also `i`, `x`, and `j`.

# Common Student Questions

What is the difference between `=` (single-equal) and `==` (double-equal)?

The `=` (single-equal) assigns the value on the right to a variable on the left. The `==` (double-equal) tests if two things have the same value, and you'll learn about this in exercise 27.

Can we write `x=100` instead of `x = 100`?

You can, but it's bad form. You should add space around operators like this so that it's easier to read.

How can I print without spaces between words in ***print***?

You do it like this: `print "Hey %s there." % "you"`. You will do more of this soon.

What do you mean by "read the file backwards"?

Very simple. Imagine you have a file with 16 lines of code in it. Start at line 16, and compare it to my file at line 16. Then do it again for 15, and so on until you've read the whole file backwards.

Why did you use **4.0** for ***space***?

It is mostly so you can then find out what a floating point number is and ask this questions. See the extra credit.

# Exercise 5: More Variables And Printing

Now we'll do even more typing of variables and printing them out. This time we'll use something called a "format string". Every time you put " (double-quotes) around a piece of text you have been making a *string*. A string is how you make something that your program might give to a human. You print them, save them to files, send them to web servers, all sorts of things.

Strings are really handy, so in this exercise you will learn how to make strings that have variables embedded in them. You embed variables inside a string by using specialized format sequences and then putting the variables at the end with a special syntax that tells Python, "Hey, this is a format string, put these variables in there."

As usual, just type this in even if you do not understand it and make it exactly the same.

```
my_name = 'Zed A. Shaw'
my_age = 35 # not a lie
my_height = 74 # inches
my_weight = 180 # lbs
my_eyes = 'Blue'
my_teeth = 'White'
my_hair = 'Brown'

print "Let's talk about %s." % my_name
print "He's %d inches tall." % my_height
print "He's %d pounds heavy." % my_weight
print "Actually that's not too heavy."
print "He's got %s eyes and %s hair." % (my_eyes, my_hair)
print "His teeth are usually %s depending on the coffee." % my_teeth

# this line is tricky, try to get it exactly right
print "If I add %d, %d, and %d I get %d." % (
    my_age, my_height, my_weight, my_age + my_height + my_weight)
```

## Warning

Remember to put # -- coding: utf-8 -- at the top if you use non-ASCII characters and get an encoding error.

# What You Should See

```
$ python ex5.py
```

```
Let's talk about Zed A. Shaw.  
He's 74 inches tall.  
He's 180 pounds heavy.  
Actually that's not too heavy.  
He's got Blue eyes and Brown hair.  
His teeth are usually White depending on the coffee.  
If I add 35, 74, and 180 I get 289.
```

# Study Drills

1. Change all the variables so there isn't the `my_` in front. Make sure you change the name everywhere, not just where you used `=` to set them.
2. Try more format characters. `%r` is a very useful one. It's like saying "print this no matter what".
3. Search online for all of the Python format characters.
4. Try to write some variables that convert the inches and pounds to centimeters and kilos. Do not just type in the measurements. Work out the math in Python.

# Common Student Questions

Can I make a variable like this: `1 = 'Zed Shaw'`?

No, the `1` is not a valid variable name. They need to start with a character, so `a1` would work, but `1` will not.

What does `%s`, `%r`, and `%d` do again?

You'll learn more about this as you continue, but they are "formatters". They tell Python to take the variable on the right, and put it in to replace the `%s` with its value.

I don't get it, what is a "formatter"? Huh?

The problem with teaching you programming is that to understand many of my descriptions you need to know how to do programming already. The way I solve this is I make you do something, and then I explain it later. When you run into these kinds of questions, write them down and see if I explain it later.

How can I round a floating point number?

You can use the `round()` function like this: `round(1.7333)`.

I get this error **`TypeError: 'str' object is not callable`**.

You probably forgot the `%` between the string and the list of variables.

Why does this not make sense to me?

Try making the numbers in this script your measurements. It's weird, but talking about yourself will make it seem more "real".

# Exercise 6: Strings And Text

While you have already been writing strings, you still do not know what they do. In this exercise we create a bunch of variables with complex strings so you can see what they are for. First an explanation of strings.

A string is usually a bit of text you want to display to someone, or "export" out of the program you are writing. Python knows you want something to be a string when you put either " (double-quotes) or ' (single-quotes) around the text. You saw this many times with your use of `print` when you put the text you want to go to the string inside " or ' after the `print`. Then Python prints it.

Strings may contain the format characters you have discovered so far. You simply put the formatted variables in the string, and then a % (percent) character, followed by the variable. The *only* catch is that if you want multiple formats in your string to print multiple variables, you need to put them inside ( ) (parenthesis) separated by , (commas). It's as if you were telling me to buy you a list of items from the store and you said, "I want milk, eggs, bread, and soup." Only as a programmer we say, "(milk, eggs, bread, soup)".

We will now type in a whole bunch of strings, variables, formats, and print them. You will also practice using short abbreviated variable names. Programmers love saving themselves time at your expense by using annoying cryptic variable names, so let's get you started being able to read and write them early on.

```
x = "There are %d types of people." % 10
binary = "binary"
do_not = "don't"
y = "Those who know %s and those who %s." % (binary, do_not)

print x
print y

print "I said: %r." % x
print "I also said: '%s'." % y

hilarious = False
joke_evaluation = "Isn't that joke so funny?! %r"

print joke_evaluation % hilarious

w = "This is the left side of..."
e = "a string with a right side."

print w + e
```

## What You Should See

```
$ python ex6.py
There are 10 types of people.
Those who know binary and those who don't.
I said: 'There are 10 types of people.'.
I also said: 'Those who know binary and those who don't.'.
Isn't that joke so funny?! False
This is the left side of...a string with a right side.
```

# Study Drills

1. Go through this program and write a comment above each line explaining it.
2. Find all the places where a string is put inside a string. There are four places.
3. Are you sure there's only four places? How do you know? Maybe I like lying.
4. Explain why adding the two strings `w` and `e` with `+` makes a longer string.

# Common Student Questions

What is the difference between `%r` and `%s`?

Use the `%r` for debugging, since it displays the "raw" data of the variable, but the others are used for displaying to users.

What's the point of `%s` and `%d` when you can just use `%r`?

The `%r` is best for debugging, and the other formats are for actually displaying variables to users.

If you thought the joke was funny could you write `hilarious = True`?

Yes, and you'll learn more about these boolean values in exercise 27.

Why do you put `'` (single-quotes) around some strings and not others?

Mostly it's because of style, but I'll use a single-quote inside a string that has double-quotes. Look at line 10 to see how I'm doing that.

I get the error **`TypeError: not all arguments converted during string formatting`**.

You need to make sure that line of code is exactly the same. What happens in this error is you have more `%` format characters in the string than variables to put in them. Go back and figure out what you did wrong.

# Exercise 7: More Printing

Now we are going to do a bunch of exercises where you just type code in and make it run. I won't be explaining much since it is just more of the same. The purpose is to build up your chops. See you in a few exercises, and *do not skip!* Do not *paste!*

```
print "Mary had a little lamb."
print "Its fleece was white as %s." % 'snow'
print "And everywhere that Mary went."
print "." * 10 # what'd that do?

end1 = "C"
end2 = "h"
end3 = "e"
end4 = "e"
end5 = "s"
end6 = "e"
end7 = "B"
end8 = "u"
end9 = "r"
end10 = "g"
end11 = "e"
end12 = "r"

# watch that comma at the end. try removing it to see what happens
print end1 + end2 + end3 + end4 + end5 + end6,
print end7 + end8 + end9 + end10 + end11 + end12
```

## What You Should See

```
$ python ex7.py
Mary had a little lamb.
Its fleece was white as snow.
And everywhere that Mary went.
.....
Cheese Burger
```

## Study Drills

For these next few exercises, you will have the exact same extra credit.

1. Go back through and write a comment on what each line does.
2. Read each one backwards or out loud to find your errors.
3. From now on, when you make mistakes write down on a piece of paper what kind of mistake you made.

4. When you go to the next exercise, look at the last mistakes you made and try not to make them in this new one.
5. Remember that everyone makes mistakes. Programmers are like magicians who like everyone to think they are perfect and never wrong, but it's all an act. They make mistakes all the time.

# Common Student Questions

How does the "end" statement work?

These are not really an "end statement", but actually the names of variables that just happen to have the word "end" in them.

Why are you using the variable named 'snow'?

That's actually not a variable, it is just a string with the word *snow* in it. A variable wouldn't have the single-quotes around it.

Is it normal to write an English comment for every line of code like you say to do in Study Drills #1?

No, normally you write comments only to explain difficult to understand code, or why you did something. Why (or your motivation) is usually much more important, and then you try to write the code so that it explains how something is being done on its own. However, sometimes you just have to write such nasty code to solve a problem that it does need a comment on every line. In this case though it's strictly for you to get better at translating from code to English.

Can I use single-quotes or double-quotes to make a string or do they do different things?

In Python either way to make a string is acceptable although typically you'll use single-quotes for any short strings like 'a' or 'snow'.

Couldn't you just not use the comma , and turn the last two lines into one single-line print?

Yes, you could very easily, but then it'd be longer than 80 characters which in Python is bad style.

# Exercise 8: Printing, Printing

```
formatter = "%r %r %r %r"

print formatter % (1, 2, 3, 4)
print formatter % ("one", "two", "three", "four")
print formatter % (True, False, False, True)
print formatter % (formatter, formatter, formatter, formatter)
print formatter % (
    "I had this thing.",
    "That you could type up right.",
    "But it didn't sing.",
    "So I said goodnight."
)
```

## What You Should See

```
$ python ex8.py
1 2 3 4
'one' 'two' 'three' 'four'
True False False True
'%r %r %r %r' '%r %r %r %r' '%r %r %r %r' '%r %r %r %r'
'I had this thing.' 'That you could type up right.' 'But it didn't sing.' 'So I said
goodnight.'
```

## Study Drills

1. Do your checks of your work, write down your mistakes, try not to make them on the next exercise.
2. Notice that the last line of output uses both single and double quotes for individual pieces. Why do you think that is?

## Common Student Questions

Should I use **%s** or **%r** for formatting?

You should use **%s** and only use **%r** for getting debugging information about something. The **%r** will give you the "raw programmer's" version of variable, also known as the "representation".

Why do I have to put quotes around "one" but not around **True** or **False**?

That's because Python recognizes **True** and **False** as keywords representing the concept of true and false. If you put

quotes around them then they are turned into strings and won't work right. You'll learn more about how these work in Exercise 27.

I tried putting Chinese (or some other non-ASCII characters) into these strings, but `%r` prints out weird symbols.

Use `%s` to print that instead and it'll work.

Why does `%r` sometimes print things with single-quotes when I wrote them with double-quotes.

Python is going to print the strings in the most efficient way it can, not replicate exactly the way you wrote them. This perfectly fine since `%r` is used for debugging and inspection, so it's not necessary that it be pretty.

Why doesn't this work in Python 3?

Don't use Python 3. Use Python 2.7 or better, although Python 2.6 might work fine.

Can I use IDLE to run this?

No, you should learn to use the command line. It is essential to learning programming and is a good place to start if you want to learn about programming. IDLE will fail for you when you get further in the book.

# Exercise 9: Printing, Printing, Printing

```
# Here's some new strange stuff, remember type it exactly.

days = "Mon Tue Wed Thu Fri Sat Sun"
months = "Jan\nFeb\nMar\nApr\nMay\nJun\nJul\nAug"

print "Here are the days: ", days
print "Here are the months: ", months

print """
There's something going on here.
With the three double-quotes.
We'll be able to type as much as we like.
Even 4 lines if we want, or 5, or 6.
"""
```

## What You Should See

```
$ python ex9.py
Here are the days:  Mon Tue Wed Thu Fri Sat Sun
Here are the months:  Jan
Feb
Mar
Apr
May
Jun
Jul
Aug

There's something going on here.
With the three double-quotes.
We'll be able to type as much as we like.
Even 4 lines if we want, or 5, or 6.
```

## Study Drills

1. Do your checks of your work, write down your mistakes, try not to make them on the next exercise.

## Common Student Questions

What if I wanted to start the months on a new line?

You simply start the string with `\n` like this: `"\nJan\nFeb\nMar\nApr\nMay\nJun\nJul\nAug"`

Why do the `\n` newlines not work when I use `%r`?

That's how `%r` formatting works, it prints it the way you wrote it (or close to it). It's the "raw" format for debugging.

I get an error when I put spaces between the three double-quotes?

You have to type them like `"""` and not `" "`, meaning with *no* spaces between each one.

Is it bad that my errors are always spelling mistakes?

Most programming errors in the beginning (and even later) are simple spelling mistakes, typos, or getting simple things out of order.

# Exercise 10: What Was That?

In Exercise 9 I threw you some new stuff, just to keep you on your toes. I showed you two ways to make a string that goes across multiple lines. In the first way, I put the characters `\n` (back-slash `n`) between the names of the months. What these two characters do is put a new `line` character into the string at that point.

This use of the `\` (back-slash) character is a way we can put difficult-to-type characters into a string. There are plenty of these "escape sequences" available for different characters you might want to put in, but there's a special one, the `double back-slash` which is just two of them `\\`. These two characters will print just one back-slash. We'll try a few of these sequences so you can see what I mean.

Another important escape sequence is to escape a single-quote `'` or double-quote `"`. Imagine you have a string that uses double-quotes and you want to put a double-quote in for the output. If you do this `"I "understand" joe."` then Python will get confused since it will think the `"` around `"understand"` actually *ends* the string. You need a way to tell Python that the `"` inside the string isn't a *real* double-quote.

To solve this problem you *escape* double-quotes and single-quotes so Python knows to include in the string. Here's an example:

```
"I am 6'2\" tall." # escape double-quote inside string
'I am 6\'2" tall.' # escape single-quote inside string
```

The second way is by using triple-quotes, which is just `"""` and works like a string, but you also can put as many lines of text as you want until you type `"""` again. We'll also play with these.

```
tabby_cat = "\tI'm tabbed in."
persian_cat = "I'm split\non a line."
backslash_cat = "I'm \\ a \\ cat."

fat_cat = """
I'll do a list:
\t* Cat food
\t* Fishies
\t* Catnip\n\t* Grass
"""

print tabby_cat
print persian_cat
print backslash_cat
print fat_cat
```

# What You Should See

Look for the tab characters that you made. In this exercise the spacing is important to get right.

```
$ python ex10.py
    I'm tabbed in.
I'm split
on a line.
I'm \ a \ cat.

I'll do a list:
    * Cat food
    * Fishies
    * Catnip
    * Grass
```

# Escape Sequences

This is the list of all of the escape sequences Python supports. You may not use many of these, but memorize their format and what they do anyway. Also try them out in some strings to see if you can make them work.

| Escape     | What it does.   |
|------------|---|
| \\         | Backslash (\)   |
| \'         | Single quote (')  |
| \"         | Double quote (")  |
| \a         | ASCII Bell (BEL)  |
| \b         | ASCII Backspace (BS)  |
| \f         | ASCII Formfeed (FF)   |
| \n         | ASCII Linefeed (LF)   |
| \N{name}   | Character named name in the Unicode database (Unicode only) |
| \r ASCII   | Carriage Return (CR)  |
| \t ASCII   | Horizontal Tab (TAB)  |
| \uxxxx     | Character with 16-bit hex value xxxx (Unicode only)         |
| \Uxxxxxxxx | Character with 32-bit hex value xxxxxxxx (Unicode only)     |
| \v         | ASCII Vertical Tab (VT)                                     |

|                   |                                |
|-------------------|--------------------------------|
| <code>\ooo</code> | Character with octal value ooo |
| <code>\xhh</code> | Character with hex value hh    |

Here's a tiny piece of fun code to try out:

```
while True:
    for i in ["/", "-", "|", "\\", "'", '"']:
        print "%s\r" % i,
```

# Study Drills

1. Memorize all the escape sequences by putting them on flash cards.
2. Use `'''` (triple-single-quote) instead. Can you see why you might use that instead of `"""`?
3. Combine escape sequences and format strings to create a more complex format.
4. Remember the `%r` format? Combine `%r` with double-quote and single-quote escapes and print them out. Compare `%r` with `%s`. Notice how `%r` prints it the way you'd write it in your file, but `%s` prints it the way you'd like to see it?

# Common Student Questions

I still haven't completely figured out the last exercise, should I continue?

Yes, keep going and instead of stopping take notes listing things you don't understand for each exercise. Periodically go through your notes and see if you can figure these things out after you've completed more exercises. Sometimes though you may need to go back a few exercises and go through them again.

What makes `\\` special compared to the other ones?

It's not special, it's simply the way you would write out one backslash (`\`) character. Think about why you would need this.

When I write `//` or `/n` it doesn't work.

That's because you are using a forward-slash `/` and not a backslash `\`. They are different characters that do very different things.

When I use a `%r` format none of the escape sequences work.

That's because `%r` is printing out the raw representation of what you typed, which is going to include the original escape sequences. Use `%s` instead. Always remember this: `%r` is for debugging, `%s` is for displaying.

I don't get Study Drills #3. What do you mean by "combine" escapes and formats?

One of the things I try to get you to understand is that each of these exercises can be combined to solve problems. Take what you know about format sequences and write some new code that uses those *and* the escapes from this exercise.

What's better, `'''` or `"""`?

It's entirely based on style. Go with the `'''` (triple-single-quote) style for now but be ready to use either depending on

what feels best or what everyone else is doing.

# Exercise 11: Asking Questions

Now it is time to pick up the pace. I have got you doing a lot of printing so that you get used to typing simple things, but those simple things are fairly boring. What we want to do now is get data into your programs. This is a little tricky because you have learn to do two things that may not make sense right away, but trust me and do it anyway. It will make sense in a few exercises.

Most of what software does is the following:

1. Take some kind of input from a person.
2. Change it.
3. Print out something to show how it changed.

So far you have only been printing, but you haven't been able to get any input from a person, or change it. You may not even know what "input" means, so rather than talk about it, let's have you do some and see if you get it. Next exercise we'll do more to explain it.

```
print "How old are you?",
age = raw_input()
print "How tall are you?",
height = raw_input()
print "How much do you weigh?",
weight = raw_input()

print "So, you're %r old, %r tall and %r heavy." % (
    age, height, weight)
```

## Note

Notice that we put a , (comma) at the end of each `print` line. This is so that `print` doesn't end the line with a newline and go to the next line.

# What You Should See

```
$ python ex11.py
How old are you? 38
How tall are you? 6'2"
How much do you weigh? 180lbs
So, you're '38' old, '6\'2"' tall and '180lbs' heavy.
```

# Study Drills

1. Go online and find out what Python's `raw_input` does.
2. Can you find other ways to use it? Try some of the samples you find.
3. Write another "form" like this to ask some other questions.
4. Related to escape sequences, try to find out why the last line has `'6\'2''` with that `\'` sequence. See how the single-quote needs to be escaped because otherwise it would end the string?

# Common Student Questions

How do I get a number from someone so I can do math?

That's a little advanced, but try `x = int(raw_input())` which gets the number as a string from `raw_input()` then converts it to an integer using `int()`.

I put my height into raw input like this `raw_input("6'2")` but it doesn't work.

You don't put your height in there, you type it directly into your terminal. First thing is, go back and make the code exactly like mine. Next, run the script, and when it pauses, type your height in at your keyboard. That's all there is to it.

Why do you have a newline on line 8 instead of putting it on one line?

That's so that the line is less than 80 characters long, which is a style that Python programmers like. You could put it on one line if you like.

What's the difference between `input()` and `raw_input()`?

The `input()` function will try to convert things you enter as if they were Python code, but it has security problems so you should avoid it.

When my strings print out there's a `u` in front of them, as in `u'35'`.

That's how Python tells you that the string is unicode. Use a `%s` format instead and you'll see it printed like normal.

# Exercise 12: Prompting People

When you typed `raw_input()` you were typing the `(` and `)` characters which are parenthesis characters. This is similar to when you used them to do a format with extra variables, as in `"%s %s" % (x, y)`. For `raw_input` you can also put in a prompt to show to a person so they know what to type. Put a string that you want for the prompt inside the `()` so that it looks like this:

```
y = raw_input("Name? ")
```

This prompts the user with "Name?" and puts the result into the variable `y`. This is how you ask someone a question and get their answer.

This means we can completely rewrite our previous exercise using just `raw_input` to do all the prompting.

```
age = raw_input("How old are you? ")
height = raw_input("How tall are you? ")
weight = raw_input("How much do you weigh? ")

print "So, you're %r old, %r tall and %r heavy." % (
    age, height, weight)
```

## What You Should See

```
$ python ex12.py
How old are you? 38
How tall are you? 6'2"
How much do you weigh? 180lbs
So, you're '38' old, '6\'2"' tall and '180lbs' heavy.
```

## Study Drills

1. In Terminal where you normally run `python` to run your scripts, type: `pydoc raw_input`. Read what it says. If you're on Windows try `python -m pydoc raw_input` instead.
2. Get out of `pydoc` by typing `q` to quit.
3. Go look online for what the `pydoc` command does.
4. Use `pydoc` to also read about `open`, `file`, `os`, and `sys`. It's alright if you do not understand those, just read through and take notes about interesting things.

# Common Student Questions

How come I get **SyntaxError: invalid syntax** whenever I run **pydoc**?

You aren't running `pydoc` from the command line, you're probably running it from inside `python`. Exit out of `python` first.

Why does my **pydoc** not pause like yours does?

Sometimes if the help document is short enough to fit on one screen then `pydoc` will just print it.

When I run **pydoc** I get **more is not recognized as an internal**.

Some versions of Windows do not have that command, which means `pydoc` is broken for you. You can skip this extra credit and just search online for Python documentation when you need it.

Why would I use **%r** over **%s**?

Remember `%r` is for debugging and is "raw representation" while `%s` is for display. I will not answer this question again so you *must* memorize this fact. This is the #1 thing people ask repeatedly, and asking the same question over and over means you aren't taking the time to memorize what you should. Stop now, and finally memorize this fact.

Why can't I do **print "How old are you?" , raw\_input()**?

You'd think that'd work, but Python doesn't recognize that as valid. The only answer I can really give is, you just can't.

# Exercise 13: Parameters, Unpacking, Variables

In this exercise we will cover one more input method you can use to pass variables to a script (script being another name for your `.py` files). You know how you type `python ex13.py` to run the `ex13.py` file? Well the `ex13.py` part of the command is called an "argument". What we'll do now is write a script that also accepts arguments.

Type this program and I'll explain it in detail:

```
from sys import argv

script, first, second, third = argv

print "The script is called:", script
print "Your first variable is:", first
print "Your second variable is:", second
print "Your third variable is:", third
```

On line 1 we have what's called an "import". This is how you add features to your script from the Python feature set. Rather than give you all the features at once, Python asks you to say what you plan to use. This keeps your programs small, but it also acts as documentation for other programmers who read your code later.

The `argv` is the "argument variable", a very standard name in programming, that you will find used in many other languages. This variable *holds* the arguments you pass to your Python script when you run it. In the exercises you will get to play with this more and see what happens.

Line 3 "unpacks" `argv` so that, rather than holding all the arguments, it gets assigned to four variables you can work with: `script`, `first`, `second`, and `third`. This may look strange, but "unpack" is probably the best word to describe what it does. It just says, "Take whatever is in `argv`, unpack it, and assign it to all of these variables on the left in order."

After that we just print them out like normal.

## Hold Up! Features Have Another Name

I call them "features" here (these little things you `import` to make your Python program do more) but nobody else calls them features. I just used that name because I needed to trick you into learning what they are without jargon. Before you

can continue, you need to learn their real name: `modules`.

From now on we will be calling these "features" that we `import` *modules*. I'll say things like, "You want to import the `sys` module." They are also called "libraries" by other programmers, but let's just stick with modules.

# What You Should See

Run the program like this (and you *must* pass *three* command line arguments):

```
$ python ex13.py first 2nd 3rd
The script is called: ex13.py
Your first variable is: first
Your second variable is: 2nd
Your third variable is: 3rd
```

This is what you should see when you do a few different runs with different arguments:

```
$ python ex13.py stuff things that
The script is called: ex13.py
Your first variable is: stuff
Your second variable is: things
Your third variable is: that
$
$ python ex13.py apple orange grapefruit
The script is called: ex13.py
Your first variable is: apple
Your second variable is: orange
Your third variable is: grapefruit
```

You can actually replace "first", "2nd", and "3rd" with any three things you want.

If you do not run it correctly, then you will get an error like this:

```
$ python ex13.py first 2nd
Traceback (most recent call last):
  File "ex13.py", line 3, in <module>
    script, first, second, third = argv
ValueError: need more than 3 values to unpack
```

This happens when you do not put enough arguments on the command when you run it (in this case just `first 2nd`). Notice when I run it I give it `first 2nd`, which caused it to give an error about "need more than 3 values to unpack" telling you that you didn't give it enough parameters.

# Study Drills

1. Try giving fewer than three arguments to your script. See that error you get? See if you can explain it.
2. Write a script that has fewer arguments and one that has more. Make sure you give the unpacked variables good names.
3. Combine `raw_input` with `argv` to make a script that gets more input from a user.

4. Remember that modules give you features. Modules. Modules. Remember this because we'll need it later.

# Common Student Questions

When I run it I get `ValueError: need more than 1 value to unpack`.

Remember that an important skill is paying attention to details. If you look at the *What You Should See* section you see that I run the script with parameters on the command line. You should replicate how I ran it exactly.

What's the difference between `argv` and `raw_input()`?

The different has to do with where the user is required to give input. If they give your script inputs on the command line, then you use `argv`. If you want them to input using the keyboard while the script is running, then use `raw_input()`.

Are the command line arguments strings?

Yes, they come in as strings, even if you typed numbers on the command line. Use `int()` to convert them just like with `raw_input()`.

How do you use the command line?

You should have learned to use it real quick by now, but if you need to learn it at this stage, then read the Command Line Crash Course I wrote for this book at <http://cli.learncodethehardway.org/book/>

I can't combine `argv` with `raw_input()`.

Don't over think it. Just slap two lines at the end of this script that uses `raw_input()` to get something and then print it. From that start playing with more ways to use both in the same script.

Why can't I do this `raw_input('? ') = x`?

Because that's backwards to how it should work. Do it the way I do it and it'll work.

# Exercise 14: Prompting And Passing

Let's do one exercise that uses `argv` and `raw_input` together to ask the user something specific. You will need this for the next exercise where we learn to read and write files. In this exercise we'll use `raw_input` slightly differently by having it just print a simple `>` prompt. This is similar to a game like Zork or Adventure.

```
from sys import argv

script, user_name = argv
prompt = '> '

print "Hi %s, I'm the %s script." % (user_name, script)
print "I'd like to ask you a few questions."
print "Do you like me %s?" % user_name
likes = raw_input(prompt)

print "Where do you live %s?" % user_name
lives = raw_input(prompt)

print "What kind of computer do you have?"
computer = raw_input(prompt)

print """
Alright, so you said %r about liking me.
You live in %r. Not sure where that is.
And you have a %r computer. Nice.
""" % (likes, lives, computer)
```

Notice though that we make a variable `prompt` that is set to the prompt we want, and we give that to `raw_input` instead of typing it over and over. Now if we want to make the prompt something else, we just change it in this one spot and rerun the script.

Very handy.

## What You Should See

When you run this, remember that you have to give the script your name for the `argv` arguments.

```
$ python ex14.py zed
Hi zed, I'm the ex14.py script.
I'd like to ask you a few questions.
Do you like me zed?
> Yes
```

```
Where do you live zed?  
> San Francisco  
What kind of computer do you have?  
> Tandy 1000  
  
Alright, so you said 'Yes' about liking me.  
You live in 'San Francisco'. Not sure where that is.  
And you have a 'Tandy 1000' computer. Nice.
```

# Study Drills

1. Find out what Zork and Adventure were. Try to find a copy and play it.
2. Change the `prompt` variable to something else entirely.
3. Add another argument and use it in your script.
4. Make sure you understand how I combined a `"""` style multi-line string with the `%` format activator as the last print.

# Common Student Questions

I get **SyntaxError: invalid syntax** when I run this script.

Again, you have to run it right on the command line, not inside python. If you type `python`, and then try to type `python ex14.py Zed` it will fail because you are running *python inside python*. Close your window and then just type `python ex14.py Zed`.

I don't understand what you mean by changing the prompt?

See the variable `prompt = '> '`. Change that to have a different value. You know this, it's just a string and you've done 13 exercises making them, so take the time to figure it out.

I get the error **ValueError: need more than 1 value to unpack**.

Remember when I said you need to look at the WYSS (What You Should See) section and replicate what I did? You need to do the same thing here and focus on how I type the command in, and why I have a command line argument.

Can I use double-quotes for the `prompt` variable?

You totally can. Go ahead and try that.

You have a Tandy computer?

I did when I was little.

I get **NameError: name 'prompt' is not defined** when I run it.

You either spelled the name of the `prompt` variable wrong or forgot that line. Go back and compare each line of code to mine, and start at the bottom of the script and work your way to the top.

How can I run this from IDLE?

Don't use IDLE.

# Exercise 15: Reading Files

Everything you've learned about `raw_input` and `argv` is so you can start reading files. You may have to play with this exercise the most to understand what's going on, so do it carefully and remember your checks. Working with files is an easy way to *erase your work* if you are not careful.

This exercise involves writing two files. One is your usual `ex15.py` file that you will run, but the *other* is named `ex15_sample.txt`. This second file isn't a script but a plain text file we'll be reading in our script. Here are the contents of that file:

```
This is stuff I typed into a file.
It is really cool stuff.
Lots and lots of fun to have in here.
```

What we want to do is "open" that file in our script and print it out. However, we do not want to just "hard code" the name `ex15_sample.txt` into our script. "Hard coding" means putting some bit of information that should come from the user as a string right in our program. That's bad because we want it to load other files later. The solution is to use `argv` and `raw_input` to ask the user what file they want instead of "hard coding" the file's name.

```
from sys import argv

script, filename = argv

txt = open(filename)

print "Here's your file %r:" % filename
print txt.read()

print "Type the filename again:"
file_again = raw_input("> ")

txt_again = open(file_again)

print txt_again.read()
```

A few fancy things are going on in this file, so let's break it down real quick:

Line 1-3 should be a familiar use of `argv` to get a filename. Next we have line 5 where we use a new command `open`. Right now, run `pydoc open` and read the instructions. Notice how like your own scripts and `raw_input`, it takes a parameter and returns a value you can set to your own variable. You just opened a file.

Line 7 we print a little line, but on line 8 we have something very new and exciting. We call a function on `txt`. What you got back from `open` is a *file*, and it's also got commands you can give it. You give a file a command by using the `.`

(dot or period), the name of the command, and parameters. Just like with `open` and `raw_input`. The difference is that when you say `txt.read()` you are saying, "Hey txt! Do your read command with no parameters!"

The remainder of the file is more of the same, but we'll leave the analysis to you in the extra credit.

# What You Should See

I made a file called "ex15\_sample.txt" and ran my script.

```
$ python ex15.py ex15_sample.txt
Here's your file 'ex15_sample.txt':
This is stuff I typed into a file.
It is really cool stuff.
Lots and lots of fun to have in here.

Type the filename again:
> ex15_sample.txt
This is stuff I typed into a file.
It is really cool stuff.
Lots and lots of fun to have in here.
```

# Study Drills

This is a big jump so be sure you do this extra credit as best you can before moving on.

1. Above each line write out in English what that line does.
2. If you are not sure ask someone for help or search online. Many times searching for "python THING" will find answers for what that THING does in Python. Try searching for "python open".
3. I used the name "commands" here, but they are also called "functions" and "methods". Search around online to see what other people do to define these. Do not worry if they confuse you. It's normal for a programmer to confuse you with their vast extensive knowledge.
4. Get rid of the part from line 10-15 where you use `raw_input` and try the script then.
5. Use only `raw_input` and try the script that way. Think of why one way of getting the filename would be better than another.
6. Run `pydoc file` and scroll down until you see the `read()` command (method/function). See all the other ones you can use? Skip the ones that have `__` (two underscores) in front because those are junk. Try some of the other commands.
7. Startup `python` again and use `open` from the prompt. Notice how you can open files and run `read` on them right there?
8. Have your script also do a `close()` on the `txt` and `txt_again` variables. It's important to close files when you are done with them.

# Common Student Questions

Does `txt = open(filename)` return the contents of the file?

No it doesn't, it actually makes something called a "file object". You can think of it like an old tape drive that you saw on mainframe computers in the 50s, or even like a DVD play from today. You can move around inside them, and then "read" them, but the file is not the contents.

I can't type code into my Terminal/PowerShell like you say in Study Drills #7.

First thing, from the command line just type `python` and hit ENTER. Now you are in `python` as we've done a few other times. Once you have that you can just type in code and python will run it in little pieces. Play with that. To get out of it type `quit()` and hit ENTER.

What does `from sys import argv` mean?

For now just understand that `sys` is a package, and this phrase just says to get the `argv` feature from that package. You'll learn more about these later.

I put the name of the file in as `script, ex15_sample.txt = argv` but it doesn't work.

No, that's not how you do it. Make the code exactly like mine, then run it from the command line the exact same way I do. You don't put the names of files in, you let Python put the name in.

Why is there no error when we open the file twice?

Python will not restrict you from opening a file more than once and in fact sometimes this is necessary.

# Exercise 16: Reading And Writing Files

If you did the extra credit from the last exercise you should have seen all sorts of commands (methods/functions) you can give to files. Here's the list of commands I want you to remember:

- `close` -- Closes the file. Like `File->Save..` in your editor.
- `read` -- Reads the contents of the file, you can assign the result to a variable.
- `readline` -- Reads just one line of a text file.
- `truncate` -- Empties the file, watch out if you care about the file.
- `write(stuff)` -- Writes stuff to the file.

For now these are the important commands you need to know. Some of them take parameters, but we do not really care about that. You only need to remember that `write` takes a parameter of a string you want to write to the file.

Let's use some of this to make a simple little text editor:

```
from sys import argv

script, filename = argv

print "We're going to erase %r." % filename
print "If you don't want that, hit CTRL-C (^C)."
```

```
print "If you do want that, hit RETURN."
```

```
raw_input("?")
```

```
print "Opening the file..."
target = open(filename, 'w')
```

```
print "Truncating the file. Goodbye!"
target.truncate()
```

```
print "Now I'm going to ask you for three lines."
```

```
line1 = raw_input("line 1: ")
line2 = raw_input("line 2: ")
line3 = raw_input("line 3: ")
```

```
print "I'm going to write these to the file."
```

```
target.write(line1)
target.write("\n")
target.write(line2)
target.write("\n")
target.write(line3)
target.write("\n")
```

```
print "And finally, we close it."
target.close()
```

That's a large file, probably the largest you have typed in. So go slow, do your checks, and make it run. One trick is to get bits of it running at a time. Get lines 1-8 running, then 5 more, then a few more, etc., until it's all done and running.

# What You Should See

There are actually two things you will see, first the output of your new script:

```
$ python ex16.py test.txt
We're going to erase 'test.txt'.
If you don't want that, hit CTRL-C (^C).
If you do want that, hit RETURN.
?
Opening the file...
Truncating the file. Goodbye!
Now I'm going to ask you for three lines.
line 1: Mary had a little lamb
line 2: It's fleece was white as snow
line 3: It was also tasty
I'm going to write these to the file.
And finally, we close it.
```

Now, open up the file you made (in my case `test.txt`) in your editor and check it out. Neat right?

# Study Drills

1. If you feel you do not understand this, go back through and use the comment trick to get it squared away in your mind. One simple English comment above each line will help you understand, or at least let you know what you need to research more.
2. Write a script similar to the last exercise that uses `read` and `argv` to read the file you just created.
3. There's too much repetition in this file. Use strings, formats, and escapes to print out `line1`, `line2`, and `line3` with just one `target.write()` command instead of 6.
4. Find out why we had to pass a `'w'` as an extra parameter to `open`. Hint: `open` tries to be safe by making you explicitly say you want to write a file.
5. If you open the file with `'w'` mode, then do you really need the `target.truncate()`? Go read the docs for Python's `open` function and see if that's true.

# Common Student Questions

Is the `truncate()` necessary with the `'w'` parameter?

See Study Drills #5.

What does `'w'` mean?

It's really just a string with a character in it for the kind of mode for the file. If you use `'w'` then you're saying "open

this file in 'write' mode", thus the 'w' character. There's also 'r' for "read", 'a' for append, and modifiers on these.

What are the modifiers to the file modes we can use?

The most important one to know for now is the + modifier, so you can do 'w+', 'r+', and 'a+'. This will open the file in both read and write mode, and depending on the character use position the file in different ways.

Does just doing `open(filename)` open it in 'r' (read) mode?

Yes, that's the default for the `open()` function.

# Exercise 17: More Files

Now let's do a few more things with files. We're going to actually write a Python script to copy one file to another. It'll be very short but will give you some ideas about other things you can do with files.

```
from sys import argv
from os.path import exists

script, from_file, to_file = argv

print "Copying from %s to %s" % (from_file, to_file)

# we could do these two on one line too, how?
in_file = open(from_file)
indata = in_file.read()

print "The input file is %d bytes long" % len(indata)

print "Does the output file exist? %r" % exists(to_file)
print "Ready, hit RETURN to continue, CTRL-C to abort."
raw_input()

out_file = open(to_file, 'w')
out_file.write(indata)

print "Alright, all done."

out_file.close()
in_file.close()
```

You should immediately notice that we import another handy command named `exists`. This returns `True` if a file exists, based on its name in a string as an argument. It returns `False` if not. We'll be using this function in the second half of this book to do lots of things, but right now you should see how you can import it.

Using `import` is a way to get tons of free code other better (well, usually) programmers have written so you do not have to write it.

## What You Should See

Just like your other scripts, run this one with two arguments, the file to copy from and the file to copy it to. I'm going to use a simple test file named `test.txt` again:

```
$ cat test.txt
This is a test file.
$
$ python ex17.py test.txt new file.txt
```

```
Copying from test.txt to new_file.txt
The input file is 21 bytes long
Does the output file exist? False
Ready, hit RETURN to continue, CTRL-C to abort.

Alright, all done.
```

It should work with any file. Try a bunch more and see what happens. Just be careful you do not blast an important file.

### Warning

Did you see that trick I did with `cat`? It only works on Linux or OSX, on Windows use `type` to do the same thing.

# Study Drills

1. Go read up on Python's `import` statement, and start `python` to try it out. Try importing some things and see if you can get it right. It's alright if you do not.
2. This script is *really* annoying. There's no need to ask you before doing the copy, and it prints too much out to the screen. Try to make it more friendly to use by removing features.
3. See how short you can make the script. I could make this 1 line long.
4. Notice at the end of the WYSS I used something called *cat*? It's an old command that "concatenates" files together, but mostly it's just an easy way to print a file to the screen. Type `man cat` to read about it.
5. Windows people, find the alternative to `cat` that Linux/OSX people have. Do not worry about `man` since there is nothing like that.
6. Find out why you had to do `output.close()` in the code.

# Common Student Questions

Why is the `'w'` in quotes?

That's a string. You've been using them for a while now, so make sure you know what a string is.

No way you can make this one line!

That ; depends ; on ; how ; you ; define ; one ; line ; of ; code.

What does the `len()` function do?

It gets the length of the string that you pass to it then returns that as a number. Play with it.

When I try to make this script shorter I get an error when I close the files at the end.

You probably did something like this `indata = open(from_file).read()` which means you don't need to then do `in_file.close()` when you reach the end of the script. It should already be closed by Python once that one line runs.

Is it normal to feel like this exercise was really hard?

Yes, it is totally normal. Programming may not "click" for you until maybe even exercise 36, or it might not until you

finish the book and then make something with Python. Everyone is different, so just keep going and keep reviewing exercises that you had trouble with until it clicks. Be patient.

I get a **SyntaxError: EOL while scanning string literal** error.

You forgot to end a string properly with a quote. Go look at that line again.

# Exercise 18: Names, Variables, Code, Functions

Big title right? I am about to introduce you to *the function*! Dum dum dah! Every programmer will go on and on about functions and all the different ideas about how they work and what they do, but I will give you the simplest explanation you can use right now.

Functions do three things:

1. They name pieces of code the way variables name strings and numbers.
2. They take arguments the way your scripts take `argv`.
3. Using #1 and #2 they let you make your own "mini scripts" or "tiny commands".

You can create a function by using the word `def` in Python. I'm going to have you make four different functions that work like your scripts, and then show you how each one is related.

```
# this one is like your scripts with argv
def print_two(*args):
    arg1, arg2 = args
    print "arg1: %r, arg2: %r" % (arg1, arg2)

# ok, that *args is actually pointless, we can just do this
def print_two_again(arg1, arg2):
    print "arg1: %r, arg2: %r" % (arg1, arg2)

# this just takes one argument
def print_one(arg1):
    print "arg1: %r" % arg1

# this one takes no arguments
def print_none():
    print "I got nothin'."

print_two("Zed", "Shaw")
print_two_again("Zed", "Shaw")
print_one("First!")
print_none()
```

Let's break down the first function, `print_two` which is the most similar to what you already know from making scripts:

1. First we tell Python we want to make a function using `def` for "define".
2. On the same line as `def` we then give the function a name, in this case we just called it "print\_two" but it could be "peanuts" too. It doesn't matter, except that your function should have a short name that says what it does.

3. Then we tell it we want `*args` (asterisk args) which is a lot like your `argv` parameter but for functions. This *has* to go inside `()` parenthesis to work.
4. Then we end this line with a `:` colon, and start indenting.
5. After the colon all the lines that are indented 4 spaces will become attached to this name, `print_two`. Our first indented line is one that unpacks the arguments the same as with your scripts.
6. To demonstrate how it works we print these arguments out, just like we would in a script.

Now, the problem with `print_two` is that it's not the easiest way to make a function. In Python we can skip the whole unpacking args and just use the names we want right inside `()`. That's what `print_two_again` does.

After that you have an example of how you make a function that takes one argument in `print_one`.

Finally you have a function that has no arguments in `print_none`.

### Warning

This is very important. Do *not* get discouraged right now if this doesn't quite make sense. We're going to do a few exercises linking functions to your scripts and show you how to make more. For now just keep thinking "mini script" when I say "function" and keep playing with them.

# What You Should See

If you run the above script you should see:

```
$ python ex18.py
arg1: 'Zed', arg2: 'Shaw'
arg1: 'Zed', arg2: 'Shaw'
arg1: 'First!'
I got nothin'.
```

Right away you can see how a function works. Notice that you used your functions the way you use things like `exists`, `open`, and other "commands". In fact, I've been tricking you because in Python those "commands" are just functions. This means you can make your own commands and use them in your scripts too.

# Study Drills

Write out a `function checklist` for later exercises. Write these on an index card and keep it by you while you complete the rest of these exercises or until you feel you do not need it:

1. Did you start your function definition with `def`?
2. Does your function name have only characters and `_` (underscore) characters?
3. Did you put an open parenthesis `(` right after the function name?
4. Did you put your arguments after the parenthesis `(` separated by commas?
5. Did you make each argument unique (meaning no duplicated names).

6. Did you put a close parenthesis and a colon `:` after the arguments?
7. Did you indent all lines of code you want in the function 4 spaces? No more, no less.
8. Did you "end" your function by going back to writing with no indent (dedenting we call it)?

And when you run ("use" or "call") a function, check these things:

1. Did you call/use/run this function by typing its name?
2. Did you put `(` character after the name to run it?
3. Did you put the values you want into the parenthesis separated by commas?
4. Did you end the function call with a `)` character?

Use these two checklists on the remaining lessons until you do not need them anymore.

Finally, repeat this a few times:

"To 'run', 'call', or 'use' a function all mean the same thing."

# Common Student Questions

What's allowed for a function name?

Just like variable names, anything that doesn't start with a number, and is letters, numbers, and underscores will work.

What does the `*` in `*args` do?

That tells python to take all the arguments to the function and then put them in args as a list. It's like `argv` that you've been using, but for functions. It's not normally used too often unless specifically needed.

This feels really boring and monotonous.

That's good, it means you're starting to get better at typing in the code and understanding what it does. To make it less boring, take everything I tell you to type in, and then break it on purpose.

# Exercise 19: Functions And Variables

Functions may have been a mind-blowing amount of information, but do not worry. Just keep doing these exercises and going through your checklist from the last exercise and you will eventually get it.

There is one tiny point though that you might not have realized which we'll reinforce right now: The variables in your function are not connected to the variables in your script. Here's an exercise to get you thinking about this:

```
def cheese_and_crackers(cheese_count, boxes_of_crackers):
    print "You have %d cheeses!" % cheese_count
    print "You have %d boxes of crackers!" % boxes_of_crackers
    print "Man that's enough for a party!"
    print "Get a blanket.\n"

print "We can just give the function numbers directly:"
cheese_and_crackers(20, 30)

print "OR, we can use variables from our script:"
amount_of_cheese = 10
amount_of_crackers = 50

cheese_and_crackers(amount_of_cheese, amount_of_crackers)

print "We can even do math inside too:"
cheese_and_crackers(10 + 20, 5 + 6)

print "And we can combine the two, variables and math:"
cheese_and_crackers(amount_of_cheese + 100, amount_of_crackers + 1000)
```

This shows all different ways we're able to give our function `cheese_and_crackers` the values it needs to print them. We can give it straight numbers. We can give it variables. We can give it math. We can even combine math and variables.

In a way, the arguments to a function are kind of like our `=` character when we make a variable. In fact, if you can use `=` to name something, you can usually pass it to a function as an argument.

## What You Should See

You should study the output of this script and compare it with what you think you should get for each of the examples in

the script.

```
$ python ex19.py
We can just give the function numbers directly:
You have 20 cheeses!
You have 30 boxes of crackers!
Man that's enough for a party!
Get a blanket.
```

```
OR, we can use variables from our script:
You have 10 cheeses!
You have 50 boxes of crackers!
Man that's enough for a party!
Get a blanket.
```

```
We can even do math inside too:
You have 30 cheeses!
You have 11 boxes of crackers!
Man that's enough for a party!
Get a blanket.
```

```
And we can combine the two, variables and math:
You have 110 cheeses!
You have 1050 boxes of crackers!
Man that's enough for a party!
Get a blanket.
```

## Study Drills

1. Go back through the script and type a comment above each line explaining in English what it does.
2. Start at the bottom and read each line backwards, saying all the important characters.
3. Write at least one more function of your own design, and run it 10 different ways.

## Common Student Questions

How can there possibly be 10 different ways to run a function?

Believe it or not, there's a theoretically infinite number of ways to call any function. In this case, do it like I've got with lines 8-12 and be creative.

Is there a way to analyze what this function is doing so I can understand it better?

There's many different ways, but try putting an English comment above each line describing what the line does.

Another trick is to read the code out loud. Yet another is to print the code out and draw on the paper with pictures and comments showing what's going on.

What if I want to ask the user for the numbers of cheese and crackers?

Remember you just need to use `int()` to convert what you get from `raw_input()`.

Does making the variables on line 13 and 14 change the variables in the function?

Nope, those variables are separate and live outside the function. They are then passed to the function and temporary versions are made just for the function's run. When the function exits these temporary variables go away and everything keeps working. Keep going in the book and this should become clearer.

Is it bad to have global variables (like on line 13 and 14) with the same name as function variables?

Yes, since then you're not quite sure which one you're talking about. But, sometimes necessity means you have to use the same name, or you might do it on accident. Just avoid it whenever you can.

Are lines 12-19 overwriting the function `cheese_and_crackers`?

No, not at all. It's calling them, which is basically a temporary jump to the first line of the function, then a jump back after the last line of the function has ended. It's not replacing the function with anything.

Is there a limit to the number of arguments a function can have?

It depends on the version of Python and the computer you're on, but it is fairly large. The practical limit though is about 5 arguments before the function becomes annoying to use.

Can you call a function within a function?

Yes, you'll make a game that does this later in the book.

# Exercise 20: Functions And Files

Remember your checklist for functions, then do this exercise paying close attention to how functions and files can work together to make useful stuff.

```
from sys import argv
script, input_file = argv

def print_all(f):
    print f.read()

def rewind(f):
    f.seek(0)

def print_a_line(line_count, f):
    print line_count, f.readline()

current_file = open(input_file)

print "First let's print the whole file:\n"

print_all(current_file)

print "Now let's rewind, kind of like a tape."

rewind(current_file)

print "Let's print three lines:"

current_line = 1
print_a_line(current_line, current_file)

current_line = current_line + 1
print_a_line(current_line, current_file)

current_line = current_line + 1
print_a_line(current_line, current_file)
```

Pay close attention to how we pass in the current line number each time we run `print_a_line`.

## What You Should See

```
$ python ex20.py test.txt
First let's print the whole file:
```

```
This is line 1
This is line 2
This is line 3

Now let's rewind, kind of like a tape.
Let's print three lines:
1 This is line 1

2 This is line 2

3 This is line 3
```

# Study Drills

1. Go through and write English comments for each line to understand what's going on.
2. Each time `print_a_line` is run you are passing in a variable `current_line`. Write out what `current_line` is equal to on each function call, and trace how it becomes `line_count` in `print_a_line`.
3. Find each place a function is used, and go check its `def` to make sure that you are giving it the right arguments.
4. Research online what the `seek` function for `file` does. Try `pydoc file` and see if you can figure it out from there.
5. Research the shorthand notation `+=` and rewrite the script to use that.

# Common Student Questions

What is `f` in the `print_all` and other functions?

The `f` is a variable just like you had in other functions in Exercise 18, except this time it's a file. A file in Python is kind of like an old tape drive on a mainframe, or maybe a DVD player. It has a "read head", and you can "seek" the this read head around the file to positions, then work with it there. Each time you do `f.seek(0)` you're moving to the start of the file. Each time you do `f.readline()` you're reading a line from the file, and moving the read head to right after the `\n` that ends that file. This will be explained more as you go on.

Why are there empty lines between the lines in the file?

The `readline()` function returns the `\n` that's in the file at the end of that line. This means that `print`'s `\n` is being added to the one already returned by `readline()`. To change this behavior simply add a `,` (comma) at the end of `print` so that it doesn't print its own `\n`.

Why does `seek(0)` not set the `current_line` to 0?

First, the `seek()` function is dealing in *bytes*, not lines. So that's going to the 0 byte (first byte) in the file. Second, `current_line` is just a variable and has no real connection to the file at all. We are manually incrementing it.

What is `+=`?

You know how in English I can rewrite "it is" to be "it's"? Or I can rewrite "you are" to "you're"? That's called a contraction, and this is kind of like a contraction for the two operations `=` and `+`. That means `x = x + y` is the same as `x += y`.

How does `readline()` know where each line is?

Inside `readline()` is code that scans each byte of the file until it finds a `\n` character, then stops reading the file to

return what it found so far. The file `f` is responsible for maintaining the current position in the file after each `readline()` call, so that it will keep reading each line.

# Exercise 21: Functions Can Return Something

You have been using the `=` character to name variables and set them to numbers or strings. We're now going to blow your mind again by showing you how to use `=` and a new Python word `return` to set variables to be a *value from a function*. There will be one thing to pay close attention to, but first type this in:

```
def add(a, b):
    print "ADDING %d + %d" % (a, b)
    return a + b

def subtract(a, b):
    print "SUBTRACTING %d - %d" % (a, b)
    return a - b

def multiply(a, b):
    print "MULTIPLYING %d * %d" % (a, b)
    return a * b

def divide(a, b):
    print "DIVIDING %d / %d" % (a, b)
    return a / b

print "Let's do some math with just functions!"

age = add(30, 5)
height = subtract(78, 4)
weight = multiply(90, 2)
iq = divide(100, 2)

print "Age: %d, Height: %d, Weight: %d, IQ: %d" % (age, height, weight, iq)

# A puzzle for the extra credit, type it in anyway.
print "Here is a puzzle."

what = add(age, subtract(height, multiply(weight, divide(iq, 2))))

print "That becomes: ", what, "Can you do it by hand?"
```

We are now doing our own math functions for `add`, `subtract`, `multiply`, and `divide`. The important thing to notice is the last line where we say `return a + b` (in `add`). What this does is the following:

1. Our function is called with two arguments: `a` and `b`.
2. We print out what our function is doing, in this case "ADDING".
3. Then we tell Python to do something kind of backward: we return the addition of `a + b`. You might say this as, "I

add a and b then return them."

4. Python adds the two numbers. Then when the function ends any line that runs it will be able to assign this `a + b` result to a variable.

As with many other things in this book, you should take this real slow, break it down and try to trace what's going on. To help there's extra credit to get you to solve a puzzle and learn something cool.

## What You Should See

```
$ python ex21.py
Let's do some math with just functions!
ADDING 30 + 5
SUBTRACTING 78 - 4
MULTIPLYING 90 * 2
DIVIDING 100 / 2
Age: 35, Height: 74, Weight: 180, IQ: 50
Here is a puzzle.
DIVIDING 50 / 2
MULTIPLYING 180 * 25
SUBTRACTING 74 - 4500
ADDING 35 + -4426
That becomes: -4391 Can you do it by hand?
```

## Study Drills

1. If you aren't really sure what `return` does, try writing a few of your own functions and have them return some values. You can return anything that you can put to the right of an `=`.
2. At the end of the script is a puzzle. I'm taking the return value of one function, and *using* it as the argument of another function. I'm doing this in a chain so that I'm kind of creating a formula using the functions. It looks really weird, but if you run the script you can see the results. What you should do is try to figure out the normal formula that would recreate this same set of operations.
3. Once you have the formula worked out for the puzzle, get in there and see what happens when you modify the parts of the functions. Try to change it on purpose to make another value.
4. Finally, do the inverse. Write out a simple formula and use the functions in the same way to calculate it.

This exercise might really whack your brain out, but take it slow and easy and treat it like a little game. Figuring out puzzles like this is what makes programming fun, so I'll be giving you more little problems like this as we go.

## Common Student Questions

Why does Python print the formula or the functions "backwards"?

It's not really backwards, it's "inside out". When you start breaking down the function into separate formulas and function calls you'll see how it works. But, try to understand what I mean by "inside out" rather than "backwards".

How can I use `raw_input()` to enter my own values?

Remember `int(raw_input())`? But, the problem with that is then you can't enter floating point, so also try using

`float(raw_input()))` instead.

What do you mean by "write out a formula"?

Try this  $24 + 34 / 100 - 1023$  as a start. Convert that to use the functions. Now come up with your own similar math equation and use variables so it's more like a formula.

# Exercise 22: What Do You Know So Far?

There won't be any code in this exercise or the next one, so there's no WYSS or Study Drills either. In fact, this exercise is like one giant Study Drills. I'm going to have you do a form of review what you have learned so far.

First, go back through every exercise you have done so far and write down every word and symbol (another name for 'character') that you have used. Make sure your list of symbols is complete.

Next to each word or symbol, write its name and what it does. If you can't find a name for a symbol in this book, then look for it online. If you do not know what a word or symbol does, then go read about it again and try using it in some code.

You may run into a few things you just can't find out or know, so just keep those on the list and be ready to look them up when you find them.

Once you have your list, spend a few days rewriting the list and double checking that it's correct. This may get boring but push through and really nail it down.

Once you have memorized the list and what they do, then you should step it up by writing out tables of symbols, their names, and what they do *from memory*. When you hit some you can't recall from memory, go back and memorize them again.

## Warning

The most important thing when doing this exercise is: "There is no failure, only trying."

# What You are Learning

It's important when you are doing a boring mindless memorization exercise like this to know why. It helps you focus on a goal and know the purpose of all your efforts.

In this exercise you are learning the names of symbols so that you can read source code more easily. It's similar to learning the alphabet and basic words of English, except this Python alphabet has extra symbols you might not know.

Just take it slow and do not hurt your brain. Hopefully by now these symbols are natural for you so this isn't a big effort. It's best to take 15 minutes at a time with your list and then take a break. Giving your brain a rest will help you learn faster with less frustration.

# Exercise 23: Read Some Code

You should have spent last week getting your list of symbols straight and locked in your mind. Now you get to apply this to another week reading code on the internet. This exercise will be daunting at first. I'm going to throw you in the deep end for a few days and have you just try your best to read and understand some source code from real projects. The goal isn't to get you to understand code, but to teach you the following three skills:

1. Finding Python source code for things you need.
2. Reading through the code and looking for files.
3. Trying to understand code you find.

At your level you really do not have the skills to evaluate the things you find, but you can benefit from getting exposure and seeing how things look.

When you do this exercise, think of yourself as an anthropologist, trucking through a new land with just barely enough of the local language to get around and survive. Except, of course, that you will actually get out alive because the internet isn't a jungle. Anyway.

Here's what you do:

1. Go to [bitbucket.org](http://bitbucket.org) with your favorite web browser and search for "python".
2. Avoid any project with "Python 3" mentioned. That'll only confuse you.
3. Pick a random project and click on it.
4. Click on the `Source` tab and browse through the list of files and directories until you find a .py file (but not `setup.py`, that's useless).
5. Start at the top and read through it, taking notes on what you think it does.
6. If any symbols or strange words seem to interest you, write them down to research later.

That's it. Your job is to use what you know so far and see if you can read the code and get a grasp of what it does. Try skimming the code first, and then read it in detail. Maybe also try taking very difficult parts and reading each symbol you know outloud.

Now try several three other sites:

- [github.com](http://github.com)
- [launchpad.net](http://launchpad.net)
- [koders.com](http://koders.com)

# Exercise 24: More Practice

You are getting to the end of this section. You should have enough Python "under your fingers" to move onto learning about how programming really works, but you should do some more practice. This exercise is longer and all about building up stamina. The next exercise will be similar. Do them, get them exactly right, and do your checks.

```
print "Let's practice everything."
print 'You\'d need to know \'bout escapes with \\ that do \n newlines and \t tabs.'
```

```
poem = """
\tThe lovely world
with logic so firmly planted
cannot discern \n the needs of love
nor comprehend passion from intuition
and requires an explanation
\n\t\twhere there is none.
"""

print "-----"
print poem
print "-----"
```

```
five = 10 - 2 + 3 - 6
print "This should be five: %s" % five
```

```
def secret_formula(started):
    jelly_beans = started * 500
    jars = jelly_beans / 1000
    crates = jars / 100
    return jelly_beans, jars, crates
```

```
start_point = 10000
beans, jars, crates = secret_formula(start_point)

print "With a starting point of: %d" % start_point
print "We'd have %d beans, %d jars, and %d crates." % (beans, jars, crates)

start_point = start_point / 10

print "We can also do that this way:"
print "We'd have %d beans, %d jars, and %d crates." % secret_formula(start_point)
```

## What You Should See

```
$ python ex24.py
Let's practice everything.
```

```
You'd need to know 'bout escapes with \ that do
newlines and tabs.
```

```
-----
```

```
    The lovely world
with logic so firmly planted
cannot discern
the needs of love
nor comprehend passion from intuition
and requires an explanation
```

```
    where there is none.
```

```
-----
```

```
This should be five: 5
With a starting point of: 10000
We'd have 5000000 beans, 5000 jars, and 50 crates.
We can also do that this way:
We'd have 500000 beans, 500 jars, and 5 crates.
```

# Study Drills

1. Make sure to do your checks: read it backwards, read it out loud, put comments above confusing parts.
2. Break the file on purpose, then run it to see what kinds of errors you get. Make sure you can fix it.

# Common Student Questions

How come you call the variable `jelly_beans` the name `beans` later?

That's part of how a function works. Remember that inside the function the variable is temporary, and when you return it then it can be assigned to a variable for later. I'm just making a new variable named `beans` to hold the return value.

What do you mean by reading the code backwards?

Start at the last line. Compare your that line in your file to the same line in mine. Once it's exactly the same, move up to the next line. Do this until you get to the first line of the file.

Who wrote that poem?

I did. Not all of my poems suck.

# Exercise 25: Even More Practice

We're going to do some more practice involving functions and variables to make sure you know them well. This exercise should be straight forward for you to type in, break down, and understand.

However, this exercise is a little different. You won't be running it. Instead *you* will import it into your python and run the functions yourself.

```
def break_words(stuff):
    """This function will break up words for us."""
    words = stuff.split(' ')
    return words

def sort_words(words):
    """Sorts the words."""
    return sorted(words)

def print_first_word(words):
    """Prints the first word after popping it off."""
    word = words.pop(0)
    print word

def print_last_word(words):
    """Prints the last word after popping it off."""
    word = words.pop(-1)
    print word

def sort_sentence(sentence):
    """Takes in a full sentence and returns the sorted words."""
    words = break_words(sentence)
    return sort_words(words)

def print_first_and_last(sentence):
    """Prints the first and last words of the sentence."""
    words = break_words(sentence)
    print_first_word(words)
    print_last_word(words)

def print_first_and_last_sorted(sentence):
    """Sorts the words then prints the first and last one."""
    words = sort_sentence(sentence)
    print_first_word(words)
    print_last_word(words)
```

First, run this like normal with `python ex25.py` to find any errors you have made. Once you have found all of the errors you can and fixed them, you will then want to follow the WYSS section to complete the exercise.

# What You Should See

In this exercise we're going to interact with your `.py` file inside the `python` interpreter you used periodically to do calculations. You run that from the shell like this:

```
$ python
Python 2.7.1 (r271:86832, Jun 16 2011, 16:59:05)
[GCC 4.2.1 (Based on Apple Inc. build 5658) (LLVM build 2335.15.00)] on darwin
Type "help", "copyright", "credits" or "license" for more information.
>>>
```

Yours will look a little different from mine, but once you see the `>>>` prompt you can then type python code in and it will run immediately.

Here's what it looks like when I do it:

```
Python 2.7.1 (r271:86832, Jun 16 2011, 16:59:05)
[GCC 4.2.1 (Based on Apple Inc. build 5658) (LLVM build 2335.15.00)] on darwin
Type "help", "copyright", "credits" or "license" for more information.
>>> import ex25
>>> sentence = "All good things come to those who wait."
>>> words = ex25.break_words(sentence)
>>> words
['All', 'good', 'things', 'come', 'to', 'those', 'who', 'wait.']
>>> sorted_words = ex25.sort_words(words)
>>> sorted_words
['All', 'come', 'good', 'things', 'those', 'to', 'wait.', 'who']
>>> ex25.print_first_word(words)
All
>>> ex25.print_last_word(words)
wait.
>>> wrods
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
NameError: name 'wrods' is not defined
>>> words
['good', 'things', 'come', 'to', 'those', 'who']
>>> ex25.print_first_word(sorted_words)
All
>>> ex25.print_last_word(sorted_words)
who
>>> sorted_words
['come', 'good', 'things', 'those', 'to', 'wait.']
>>> sorted_words = ex25.sort_sentence(sentence)
>>> sorted_words
['All', 'come', 'good', 'things', 'those', 'to', 'wait.', 'who']
>>> ex25.print_first_and_last(sentence)
All
wait.
>>> ex25.print_first_and_last_sorted(sentence)
All
who
```

Let's break this down line by line to make sure you know what's going on:

- Line 5 you import *your* `ex25.py` python file, just like other imports you have done. Notice you do not need to put the `.py` at the end to import it. When you do this you make a `module` that has all your functions in it to use.

Line 6 you made a sentence to work with.

- Line 7 you use the `ex25` module and call your first function `ex25.break_words`. The `.` (dot, period) symbol is how you tell python, "Hey, inside `ex25` there's a function called `break_words` and I want to run it."
- Line 8 we just type `words`, and python will print out what's in that variable (line 9). It looks weird but this is a `list` which you will learn about later.
- Lines 10-11 we do the same thing with `ex25.sort_words` to get a sorted sentence.
- Lines 13-16 we use `ex25.print_first_word` and `ex25.print_last_word` to get the first and last word printed out.
- Line 17 is interesting. I made a mistake and typed the `words` variable as `wrods` so python gave me an error on Lines 18-20.
- Line 21-22 is where we print the modified words list. Notice that since we printed the first and last one, those words are now missing.

The remaining lines are for you to figure out and analyze in the extra credit.

## Study Drills

1. Take the remaining lines of the WYSS output and figure out what they are doing. Make sure you understand how you are running your functions in the `ex25` module.
2. Try doing this: `help(ex25)` and also `help(ex25.break_words)`. Notice how you get help for your module, and how the help is those odd `"""` strings you put after each function in `ex25`? Those special strings are called `documentation comments` and we'll be seeing more of them.
3. Typing `ex25.` is annoying. A shortcut is to do your import like this: `from ex25 import *` which is like saying, "Import everything from `ex25`." Programmers like saying things backwards. Start a new session and see how all your functions are right there.
4. Try breaking your file and see what it looks like in `python` when you use it. You will have to quit python with CTRL-D (CTRL-Z on windows) to be able to reload it.

## Common Student Questions

I get a **None** printed out for some of the functions.

You probalby have a function that is missing the `return` at the end. Go backwards through the file like I taught you and confirm that every line is right.

I get **-bash: import: command not found** when I type `import ex15`.

Pay attention to what I'm doing in the *What You Should See* section. I'm doing this in *python* not in the terminal. That means you first run python.

I get **ImportError: No module named ex25.py** when I type `import ex25.py`.

Don't add the `.py` to the end. Python know's the file ends in `.py` so you just type `import ex25`.

I get **SyntaxError: invalid syntax** when I run this.

That means you have something like a missing `(` or `"` or similar syntax error on that line or above it. Any time you get that error, start at the line it mentions and check that it's right, then go backwards checking each line above that.

I thought code in a function only impacts that function. How can the `words.pop(0)` be changing the `words` variable then?

That's a complicated question, but in this case `words` is a list, and because of that you can give it commands and it'll retain the results of those commands. This is similar to how files and many other things worked when you were working with `f.readline()`.

When should I `print` vs. `return` in a function?

You need to understand that `print` is only for printing to the screen, and that you can actually do both `print` and `return` a value. When you understand this then you'll see that the question is kind of a pointless question. You use `print` when you want to print. You use `return` when you want to return.

# Exercise 26: Congratulations, Take A Test!

You are almost done with the first half of the book. The second half is where things get interesting. You will learn logic and be able to do useful things like make decisions.

Before you continue, I have a quiz for you. This quiz will be *very* hard because it requires you to fix someone else's code. When you are a programmer you often have to deal with another programmer's code, and also with their arrogance. They will very frequently claim that their code is perfect.

These programmers are stupid people who care little for others. A good programmer assumes, like a good scientist, that there's always *some* probability their code is wrong. Good programmers start from the premise that their software is broken and then work to rule out all possible ways it could be wrong before finally admitting that maybe it really is the other guy's code.

In this exercise, you will practice dealing with a bad programmer by fixing a bad programmer's code. I have poorly copied exercises 24 and 25 into a file and removed random characters and added flaws. Most of the errors are things Python will tell you, while some of them are math errors you should find. Others are formatting errors or spelling mistakes in the strings.

All of these errors are very common mistakes all programmers make. Even experienced ones.

Your job in this exercise is to correct this file. Use all of your skills to make this file better. Analyze it first, maybe printing it out to edit it like you would a school term paper. Fix each flaw and keep running it and fixing it until the script runs perfectly. Try not to get help, and instead if you get stuck take a break and come back to it later.

Even if this takes days to do, bust through it and make it right.

Finally, the point of this exercise isn't to type it in, but to fix an existing file. To do that, you must go to:

- <http://learnpythonthehardway.org/book/exercise26.txt>

Copy-paste the code into a file named `ex26.py`. This is the only time you are allowed to copy-paste.

## Common Student Questions

Do I have to import **ex25.py** or can I just remove the references to it?

You can do either. This file has the functions from `ex25` though, so first go with removing references to it.

Can we run the code while we're fixing it?

You most certainly may. The computer is there to help, so use it as much as possible.

# Exercise 27: Memorizing Logic

Today is the day you start learning about logic. Up to this point you have done everything you possibly can reading and writing files, to the terminal, and have learned quite a lot of the math capabilities of Python.

From now on, you will be learning *logic*. You won't learn complex theories that academics love to study, but just the simple basic logic that makes real programs work and that real programmers need every day.

Learning logic has to come after you do some memorization. I want you to do this exercise for an entire week. Do not falter. Even if you are bored out of your mind, keep doing it. This exercise has a set of logic tables you must memorize to make it easier for you to do the later exercises.

I'm warning you this won't be fun at first. It will be downright boring and tedious but this is to teach you a very important skill you will need as a programmer. You *will* need to be able to memorize important concepts as you go in your life. Most of these concepts will be exciting once you get them. You will struggle with them, like wrestling a squid, then one day *snap* you will understand it. All that work memorizing the basics pays off big later.

Here's a tip on how to memorize something without going insane: Do a tiny bit at a time throughout the day and mark down what you need to work on most. Do not try to sit down for two hours straight and memorize these tables. This won't work. Your brain will really only retain whatever you studied in the first 15 or 30 minutes anyway.

Instead, what you should do is create a bunch of index cards with each column on the left on one side (True or False) and the column on the right on the back. You should then pull them out, see the "True or False" and be able to immediately say "True!" Keep practicing until you can do this.

Once you can do that, start writing out your own truth tables each night into a notebook. Do not just copy them. Try to do them from memory, and when you get stuck glance quickly at the ones I have here to refresh your memory. Doing this will train your brain to remember the whole table.

Do not spend more than one week on this, because you will be applying it as you go.

## The Truth Terms

In python we have the following terms (characters and phrases) for determining if something is "True" or "False". Logic on a computer is all about seeing if some combination of these characters and some variables is True at that point in the program.

- and

- or
- not
- != (not equal)
- == (equal)
- >= (greater-than-equal)
- <= (less-than-equal)
- True
- False

You actually have run into these characters before, but maybe not the phrases. The phrases (and, or, not) actually work the way you expect them to, just like in English.

# The Truth Tables

We will now use these characters to make the truth tables you need to memorize.

| NOT       | True? |
|-----------|-------|
| not False | True  |
| not True  | False |

| OR             | True? |
|----------------|-------|
| True or False  | True  |
| True or True   | True  |
| False or True  | True  |
| False or False | False |

| AND             | True? |
|-----------------|-------|
| True and False  | False |
| True and True   | True  |
| False and True  | False |
| False and False | False |

| NOT OR | True? |
|--------|-------|
|--------|-------|

|                      |       |
|----------------------|-------|
| not (True or False)  | False |
| not (True or True)   | False |
| not (False or True)  | False |
| not (False or False) | True  |

| NOT AND               | True? |
|-----------------------|-------|
| not (True and False)  | True  |
| not (True and True)   | False |
| not (False and True)  | True  |
| not (False and False) | True  |

| !=     | True? |
|--------|-------|
| 1 != 0 | True  |
| 1 != 1 | False |
| 0 != 1 | True  |
| 0 != 0 | False |

| ==     | True? |
|--------|-------|
| 1 == 0 | False |
| 1 == 1 | True  |
| 0 == 1 | False |
| 0 == 0 | True  |

Now use these tables to write up your own cards and spend the week memorizing them. Remember though, there is no failing in this book, just trying as hard as you can each day, and then a *little* bit more.

# Common Student Questions

Can't I just learn the concepts behind boolean algebra and not memorize this?

Sure, you can do that, but then you'll have to constantly go through the rules to boolean algebra while you code. If you memorize these first, it not only builds your memorization skills, but it also makes these operations natural. After that, the concept of boolean algebra is easy. But, do whatever works for you.

# Exercise 28: Boolean Practice

The logic combinations you learned from the last exercise are called "boolean" logic expressions. Boolean logic is used *everywhere* in programming. They are essential fundamental parts of computation and knowing them very well is akin to knowing your scales in music.

In this exercise you will be taking the logic exercises you memorized and start trying them out in `python`. Take each of these logic problems, and write out what you think the answer will be. In each case it will be either `True` or `False`. Once you have the answers written down, you will start `python` in your terminal and type them in to confirm your answers.

1. `True and True`
2. `False and True`
3. `1 == 1 and 2 == 1`
4. `"test" == "test"`
5. `1 == 1 or 2 != 1`
6. `True and 1 == 1`
7. `False and 0 != 0`
8. `True or 1 == 1`
9. `"test" == "testing"`
10. `1 != 0 and 2 == 1`
11. `"test" != "testing"`
12. `"test" == 1`
13. `not (True and False)`
14. `not (1 == 1 and 0 != 1)`
15. `not (10 == 1 or 1000 == 1000)`
16. `not (1 != 10 or 3 == 4)`
17. `not ("testing" == "testing" and "Zed" == "Cool Guy")`
18. `1 == 1 and not ("testing" == 1 or 1 == 0)`
19. `"chunky" == "bacon" and not (3 == 4 or 3 == 3)`
20. `3 == 3 and not ("testing" == "testing" or "Python" == "Fun")`

I will also give you a trick to help you figure out the more complicated ones toward the end.

Whenever you see these boolean logic statements, you can solve them easily by this simple process:

1. Find equality test (`==` or `!=`) and replace it with its truth.
2. Find each and/or inside a parenthesis and solve those first.
3. Find each not and invert it.

4. Find any remaining and/or and solve it.
5. When you are done you should have True or False.

I will demonstrate with a variation on #20:

```
3 != 4 and not ("testing" != "test" or "Python" == "Python")
```

Here's me going through each of the steps and showing you the translation until I've boiled it down to a single result:

1. Solve each equality test:

1. `3 != 4` is True: True and not (`"testing" != "test"` or `"Python" == "Python"`)
2. `"testing" != "test"` is True: True and not (`True` or `"Python" == "Python"`)
3. `"Python" == "Python"`: True and not (`True` or `True`)

2. Find each and/or in parenthesis ():

1. (`True` or `True`) is True: True and not (`True`)

3. Find each not and invert it:

1. not (`True`) is False: True and False

4. Find any remaining and/or and solve them:

1. True and False is False

With that we're done and know the result is False.

### Warning

The more complicated ones may seem *very* hard at first. You should be able to give a good first stab at solving them, but do not get discouraged. I'm just getting you primed for more of these "logic gymnastics" so that later cool stuff is much easier. Just stick with it, and keep track of what you get wrong, but do not worry that it's not getting in your head quite yet. It'll come.

# What You Should See

After you have tried to guess at these, this is what your session with `python` might look like:

```
$ python
Python 2.5.1 (r251:54863, Feb 6 2009, 19:02:12)
[GCC 4.0.1 (Apple Inc. build 5465)] on darwin
Type "help", "copyright", "credits" or "license" for more information.
>>> True and True
True
>>> 1 == 1 and 2 == 2
True
```

# Study Drills

1. There are a lot of operators in Python similar to `!=` and `==`. Try to find out as many "equality operators" as you can. They should be like: `<` or `<=`.
2. Write out the names of each of these equality operators. For example, I call `!=` "not equal".
3. Play with the `python` by typing out new boolean operators, and before you hit enter try to shout out what it is. Do not think about it, just the first thing that comes to mind. Write it down then hit enter, and keep track of how many you get right and wrong.
4. Throw away that piece of paper from #3 away so you do not accidentally try to use it later.

# Common Student Questions

Why does `"test" and "test"` return `"test"` or `1 and 1` return `1` instead of `True`?

Python and many languages like it return one of the operands to their boolean expressions rather than just `True` or `False`. This means that if you did `False and 1` you get the first operand (`False`) but if you do `True and 1` you get the second (`1`). Play with this a bit.

Is there any difference between `!=` and `<>`?

Python has deprecated `<>` in favor of `!=`, so use `!=`. Other than that there should be no difference.

Isn't there a shortcut?

Yes. Any `and` expression that has a `False` is immediately `False`, so you can stop there. Any `or` expression that has a `True` is immediately `True`, so you can stop there. But make sure that you can process the whole expression because later it becomes helpful.

# Exercise 29: What If

Here is the next script of Python you will enter, which introduces you to the `if`-statement. Type this in, make it run exactly right, and then we'll try see if your practice has paid off.

```
people = 20
cats = 30
dogs = 15

if people < cats:
    print "Too many cats! The world is doomed!"

if people > cats:
    print "Not many cats! The world is saved!"

if people < dogs:
    print "The world is drooled on!"

if people > dogs:
    print "The world is dry!"

dogs += 5

if people >= dogs:
    print "People are greater than or equal to dogs."

if people <= dogs:
    print "People are less than or equal to dogs."

if people == dogs:
    print "People are dogs."
```

## What You Should See

```
$ python ex29.py
Too many cats! The world is doomed!
The world is dry!
People are greater than or equal to dogs.
People are less than or equal to dogs.
People are dogs.
```

## Study Drills

In this extra credit, try to guess what you think the `if`-statement is and what it does. Try to answer these questions in your own words before moving onto the next exercise:

1. What do you think the `if` does to the code under it?
2. Why does the code under the `if` need to be indented 4 spaces?
3. What happens if it isn't indented?
4. Can you put other boolean expressions from Ex. 27 in the `if`-statement? Try it.
5. What happens if you change the initial variables for `people`, `cats`, and `dogs`?

# Common Student Questions

What does `+=` mean?

The code `x += 1` is the same as doing `x = x + 1` but involves less typing. You can call this the "increment by" operator. Same goes for `-=` and many other expressions you'll learn later.

# Exercise 30: Else And If

In the last exercise you worked out some `if`-statements, and then tried to guess what they are and how they work. Before you learn more I'll explain what everything is by answering the questions you had from extra credit. You did the extra credit right?

1. What do you think the `if` does to the code under it? An if statement creates what is called a "branch" in the code. It's kind of like those choose your own adventure books where you are asked to turn to one page if you make one choice, and another if you go a different direction. The `if`-statement tells your script, "If this boolean expression is True, then run the code under it, otherwise skip it."
2. Why does the code under the `if` need to be indented 4 spaces? A colon at the end of a line is how you tell Python you are going to create a new "block" of code, and then indenting 4 spaces tells Python what lines of code are in that block. This is *exactly* the same thing you did when you made functions in the first half of the book.
3. What happens if it isn't indented? If it isn't indented, you will most likely create a Python error. Python expects you to indent *something* after you end a line with a `:` (colon).
4. Can you put other boolean expressions from Ex. 27 in the `if` statement? Try it. Yes you can, and they can be as complex as you like, although really complex things generally are bad style.
5. What happens if you change the initial values for `people`, `cats`, and `dogs`? Because you are comparing numbers, if you change the numbers, different `if`-statements will evaluate to `True` and the blocks of code under them will run. Go back and put different numbers in and see if you can figure out in your head what blocks of code will run.

Compare my answers to your answers, and make sure you *really* understand the concept of a "block" of code. This is important for when you do the next exercise where you write all the parts of `if`-statements that you can use.

Type this one in and make it work too.

```
people = 30
cars = 40
buses = 15

if cars > people:
    print "We should take the cars."
elif cars < people:
    print "We should not take the cars."
else:
    print "We can't decide."

if buses > cars:
    print "That's too many buses."
elif buses < cars:
    print "Maybe we could take the buses."
```

```
else:
    print "We still can't decide."

if people > buses:
    print "Alright, let's just take the buses."
else:
    print "Fine, let's stay home then."
```

# What You Should See

```
$ python ex30.py
We should take the cars.
Maybe we could take the buses.
Alright, let's just take the buses.
```

# Study Drills

1. Try to guess what `elif` and `else` are doing.
2. Change the numbers of `cars`, `people`, and `buses` and then trace through each `if`-statement to see what will be printed.
3. Try some more complex boolean expressions like `cars > people` and `buses < cars`.
4. Above each line write an English description of what the line does.

# Common Student Questions

What happens if multiple `elif` blocks are `True`?

Python starts at the top and runs the first block that is `True`, so it will run only the first one.

# Exercise 31: Making Decisions

In the first half of this book you mostly just printed out things and called functions, but everything was basically in a straight line. Your scripts ran starting at the top, and went to the bottom where they ended. If you made a function you could run that function later, but it still didn't have the kind of branching you need to really make decisions. Now that you have `if`, `else`, and `elif` you can start to make scripts that decide things.

In the last script you wrote out a simple set of tests asking some questions. In this script you will ask the user questions and make decisions based on their answers. Write this script, and then play with it quite a lot to figure it out.

```
print "You enter a dark room with two doors.  Do you go through door #1 or door #2?"

door = raw_input("> ")

if door == "1":
    print "There's a giant bear here eating a cheese cake.  What do you do?"
    print "1. Take the cake."
    print "2. Scream at the bear."

    bear = raw_input("> ")

    if bear == "1":
        print "The bear eats your face off.  Good job!"
    elif bear == "2":
        print "The bear eats your legs off.  Good job!"
    else:
        print "Well, doing %s is probably better.  Bear runs away." % bear

elif door == "2":
    print "You stare into the endless abyss at Cthulhu's retina."
    print "1. Blueberries."
    print "2. Yellow jacket clothespins."
    print "3. Understanding revolvers yelling melodies."

    insanity = raw_input("> ")

    if insanity == "1" or insanity == "2":
        print "Your body survives powered by a mind of jello.  Good job!"
    else:
        print "The insanity rots your eyes into a pool of muck.  Good job!"

else:
    print "You stumble around and fall on a knife and die.  Good job!"
```

A key point here is that you are now putting the `if`-statements *inside* `if`-statements as code that can run. This is very powerful and can be used to create "nested" decisions, where one branch leads to another and another.

Make sure you understand this concept of `if`-statements inside `if`-statements. In fact, do the extra credit to really nail it.

# What You Should See

Here is me playing this little adventure game. I do not do so well.

```
$ python ex31.py
You enter a dark room with two doors.  Do you go through door #1 or door #2?
> 1
There's a giant bear here eating a cheese cake.  What do you do?
1. Take the cake.
2. Scream at the bear.
> 2
The bear eats your legs off.  Good job!
```

## Study Drills

Make new parts of the game and change what decisions people can make. Expand the game out as much as you can before it gets ridiculous.

## Common Student Questions

Can you just replace **elif** with a sequence of **if/else** combinations?

You can in some situations, but it depends on how each **if/else** is written. It also means that Python will check *every* **if/else** combination, rather than just the first false ones like it would with **if/elif/else**. Try to make some of these to figure out the differences.

How do I tell if a number is between a range of numbers?

You have two options: Use `0 < x < 10` or `1 <= x < 10` which is classic notation, or use `x in range(1, 10)`.

What if I wanted more options in the **if/elif/else** blocks?

Easy, just add more **elif** blocks for each possible choice.

# Exercise 32: Loops And Lists

You should now be able to do some programs that are much more interesting. If you have been keeping up, you should realize that now you can combine all the other things you have learned with `if-statements` and boolean expressions to make your programs do smart things.

However, programs also need to do repetitive things very quickly. We are going to use a `for-loop` in this exercise to build and print various lists. When you do the exercise, you will start to figure out what they are. I won't tell you right now. You have to figure it out.

Before you can use a `for-loop`, you need a way to *store* the results of loops somewhere. The best way to do this is with a *list*. A list is exactly what its name says, a container of things that are organized in order. It's not complicated; you just have to learn a new syntax. First, there's how you make a list:

```
hairs = ['brown', 'blond', 'red']
eyes = ['brown', 'blue', 'green']
weights = [1, 2, 3, 4]
```

What you do is start the list with the `[` (left-bracket) which "opens" the list. Then you put each item you want in the list separated by commas, just like when you did function arguments. Lastly you end the list with a `]` (right-bracket) to indicate that it's over. Python then takes this list and all its contents, and assigns them to the variable.

## Warning

This is where things get tricky for people who can't program. Your brain has been taught that the world is flat. Remember in the last exercise where you put `if-statements` inside `if-statements`? That probably made your brain hurt because most people do not ponder how to "nest" things inside things. In programming this is all over the place. You will find functions that call other functions that have `if-statements` that have lists with lists inside lists. If you see a structure like this that you can't figure out, take out pencil and paper and break it down manually bit by bit until you understand it.

We now will build some lists using some loops and print them out:

```
the_count = [1, 2, 3, 4, 5]
fruits = ['apples', 'oranges', 'pears', 'apricots']
change = [1, 'pennies', 2, 'dimes', 3, 'quarters']

# this first kind of for-loop goes through a list
for number in the_count:
```

```

print "This is count %d" % number

# same as above
for fruit in fruits:
    print "A fruit of type: %s" % fruit

# also we can go through mixed lists too
# notice we have to use %r since we don't know what's in it
for i in change:
    print "I got %r" % i

# we can also build lists, first start with an empty one
elements = []

# then use the range function to do 0 to 5 counts
for i in range(0, 6):
    print "Adding %d to the list." % i
    # append is a function that lists understand
    elements.append(i)

# now we can print them out too
for i in elements:
    print "Element was: %d" % i

```

# What You Should See

```

$ python ex32.py
This is count 1
This is count 2
This is count 3
This is count 4
This is count 5
A fruit of type: apples
A fruit of type: oranges
A fruit of type: pears
A fruit of type: apricots
I got 1
I got 'pennies'
I got 2
I got 'dimes'
I got 3
I got 'quarters'
Adding 0 to the list.
Adding 1 to the list.
Adding 2 to the list.
Adding 3 to the list.
Adding 4 to the list.
Adding 5 to the list.
Element was: 0
Element was: 1
Element was: 2
Element was: 3
Element was: 4
Element was: 5

```

# Study Drills

1. Take a look at how you used `range`. Look up the `range` function to understand it.
2. Could you have avoided that `for`-loop entirely on line 22 and just assigned `range(0, 6)` directly to `elements`?
3. Find the Python documentation on lists and read about them. What other operations can you do to lists besides

append?

# Common Student Questions

How do you make a 2-dimensional (2D) list?

That's a list in a list like this: `[[1,2,3],[4,5,6]]`

Aren't lists and arrays the same thing?

Depends on the language and the implementation. In classic terms a list is very different from an array because of how they're implemented. In Ruby though they call these arrays. In Python they call them lists. Just call these lists for now since that's what Python calls them.

How come a for-loop can use variables that aren't defined yet?

It defines that variable, initializing it to the current element of the loop iteration, each time through.

Why does `for i in range(1, 3):` only loop 2 times instead of 3 times?

The `range()` function only does numbers from the first to the last, *not including the last*. So it stops at 2, not 3 in the above. This turns out to be the most common way to do this kind of loop.

What does `elements.append()` do?

It simply appends to the end of the list. Open up the Python shell and try a few examples with a list you make. Any time you run into things like this, always try to play with them interactively in the Python shell.

# Exercise 33: While Loops

Now to totally blow your mind with a new loop, the `while`-loop. A `while`-loop will keep executing the code block under it as long as a boolean expression is `True`.

Wait, you have been keeping up with the terminology right? That if we write a line and end it with a `:` (colon) then that tells Python to start a new block of code? Then we indent and that's the new code. This is all about structuring your programs so that Python knows what you mean. If you do not get that idea then go back and do some more work with `if`-statements, functions, and the `for`-loop until you get it.

Later on we'll have some exercises that will train your brain to read these structures, similar to how we burned boolean expressions into your brain.

Back to `while`-loops. What they do is simply do a test like an `if`-statement, but instead of running the code block *once*, they jump back to the "top" where the `while` is, and repeat. It keeps doing this until the expression is `False`.

Here's the problem with `while`-loops: Sometimes they do not stop. This is great if your intention is to just keep looping until the end of the universe. Otherwise you almost always want your loops to end eventually.

To avoid these problems, there's some rules to follow:

1. Make sure that you use `while`-loops sparingly. Usually a `for`-loop is better.
2. Review your `while` statements and make sure that the thing you are testing will become `False` at some point.
3. When in doubt, print out your test variable at the top and bottom of the `while`-loop to see what it's doing.

In this exercise, you will learn the `while`-loop by doing the above three things:

```
i = 0
numbers = []

while i < 6:
    print "At the top i is %d" % i
    numbers.append(i)

    i = i + 1
    print "Numbers now: ", numbers
    print "At the bottom i is %d" % i

print "The numbers: "

for num in numbers:
    print num
```

# What You Should See

```
$ python ex33.py
At the top i is 0
Numbers now: [0]
At the bottom i is 1
At the top i is 1
Numbers now: [0, 1]
At the bottom i is 2
At the top i is 2
Numbers now: [0, 1, 2]
At the bottom i is 3
At the top i is 3
Numbers now: [0, 1, 2, 3]
At the bottom i is 4
At the top i is 4
Numbers now: [0, 1, 2, 3, 4]
At the bottom i is 5
At the top i is 5
Numbers now: [0, 1, 2, 3, 4, 5]
At the bottom i is 6
The numbers:
0
1
2
3
4
5
```

## Study Drills

1. Convert this while loop to a function that you can call, and replace 6 in the test (`i < 6`) with a variable.
2. Now use this function to rewrite the script to try different numbers.
3. Add another variable to the function arguments that you can pass in that lets you change the `+ 1` on line 8 so you can change how much it increments by.
4. Rewrite the script again to use this function to see what effect that has.
5. Now, write it to use `for-loops` and `range` instead. Do you need the incrementor in the middle anymore? What happens if you do not get rid of it?

If at any time that you are doing this it goes crazy (it probably will), just hold down `CTRL` and hit `c` (`CTRL-c`) and the program will abort.

## Common Student Questions

What's the difference between a **for-loop** and a **while-loop**?

A `for-loop` can only iterate (loop) "over" collections of things. A `while-loop` can do any kind of iteration (looping) you want. However, `while-loops` are harder to get right and you normally can get many things done with `for-loops`.

Loops are hard, how do I figure them out?

The main reason people don't understand loops is because they can't follow the "jumping" that the code does. When a loop runs it goes through its block of code, and at the end it jumps back to the top. To visualize this, put print statements all over the loop printing out where in the loop Python is running and what the variables are set to at those points. Put prints before the loop, at the top of the loop, in the middle, and at the bottom. Study the output and try to understand the jumping that's going on.

# Exercise 34: Accessing Elements Of Lists

Lists are pretty useful, but unless you can get at the things in them they aren't all that good. You can already go through the elements of a list in order, but what if you want say, the 5th element? You need to know how to access the elements of a list. Here's how you would access the *first* element of a list:

```
animals = ['bear', 'tiger', 'penguin', 'zebra']
bear = animals[0]
```

You take a list of animals, and then you get the first one using 0?! How does that work? Because of the way math works, Python start its lists at 0 rather than 1. It seems weird, but there's many advantages to this, even though it is mostly arbitrary.

The best way to explain why is by showing you the difference between how you use numbers and how programmers use numbers.

Imagine you are watching the four animals in our list above (['bear', 'tiger', 'penguin', 'zebra']) run in a race. They win in the *order* we have them in this list. The race was really exciting because, the animals didn't eat each other and somehow managed to run a race. Your friend however shows up late and wants to know who won. Does your friend say, "Hey, who came in *zeroth*?" No, he says, "Hey, who came in *first*?"

This is because the *order* of the animals is important. You can't have the second animal without the first animal, and can't have the third without the second. It's also impossible to have a "zeroth" animal since zero means nothing. How can you have a nothing win a race? It just doesn't make sense. We call these kinds of numbers "ordinal" numbers, because they indicate an ordering of things.

Programmers, however, can't think this way because they can pick any element out of a list at any point. To a programmer, the above list is more like a deck of cards. If they want the tiger, they grab it. If they want the zebra, they can take it too. This need to pull elements out of lists at random means that they need a way to indicate elements consistently by an address, or an "index", and the best way to do that is to start the indices at 0. Trust me on this, the math is way easier for these kinds of accesses. This kind of number is a "cardinal" number and means you can pick at random, so there needs to be a 0 element.

So, how does this help you work with lists? Simple, every time you say to yourself, "I want the 3rd animal," you translate this "ordinal" number to a "cardinal" number by subtracting 1. The "3rd" animal is at index 2 and is the penguin. You have to do this because you have spent your whole life using ordinal numbers, and now you have to think in cardinal.

Just subtract 1 and you will be good.

Remember: ordinal == ordered, 1st; cardinal == cards at random, 0.

Let's practice this. Take this list of animals, and follow the exercises where I tell you to write down what animal you get for that ordinal or cardinal number. Remember if I say "first", "second", etc. then I'm using ordinal, so subtract 1. If I give you cardinal (0, 1, 2) then use it directly.

```
animals = ['bear', 'python', 'peacock', 'kangaroo', 'whale', 'platypus']
```

1. The animal at 1.
2. The 3rd animal.
3. The 1st animal.
4. The animal at 3.
5. The 5th animal.
6. The animal at 2.
7. The 6th animal.
8. The animal at 4.

For each of these, write out a full sentence of the form: "The 1st animal is at 0 and is a bear." Then say it backwards, "The animal at 0 is the 1st animal and is a bear."

Use your python to check your answers.

# Study Drills

1. Read about ordinal and cardinal numbers online.
2. With what you know of the difference between these types of numbers, can you explain why the year 2010 in "January 1, 2010" really is 2010 and not 2009? (Hint, you can't pick years at random.)
3. Write some more lists and work out similar indexes until you can translate them.
4. Use Python to check your answers to this as well.

## Warning

Programmers will tell you to read this guy named "Dijkstra" on this subject. I recommend you avoid his writings on this unless you enjoy being yelled at by someone who stopped programming at the same time programming started.

# Exercise 35: Branches and Functions

You have learned to do `if`-statements, functions, and lists. Now it's time to bend your mind. Type this in, and see if you can figure out what it's doing.

```
from sys import exit

def gold_room():
    print "This room is full of gold.  How much do you take?"

    next = raw_input("> ")
    if "0" in next or "1" in next:
        how_much = int(next)
    else:
        dead("Man, learn to type a number.")

    if how_much < 50:
        print "Nice, you're not greedy, you win!"
        exit(0)
    else:
        dead("You greedy bastard!")

def bear_room():
    print "There is a bear here."
    print "The bear has a bunch of honey."
    print "The fat bear is in front of another door."
    print "How are you going to move the bear?"
    bear_moved = False

    while True:
        next = raw_input("> ")

        if next == "take honey":
            dead("The bear looks at you then slaps your face off.")
        elif next == "taunt bear" and not bear_moved:
            print "The bear has moved from the door. You can go through it now."
            bear_moved = True
        elif next == "taunt bear" and bear_moved:
            dead("The bear gets pissed off and chews your leg off.")
        elif next == "open door" and bear_moved:
            gold_room()
        else:
            print "I got no idea what that means."

def cthulhu_room():
    print "Here you see the great evil Cthulhu."
    print "He, it, whatever stares at you and you go insane."
    print "Do you flee for your life or eat your head?"
```

```

next = raw_input("> ")

if "flee" in next:
    start()
elif "head" in next:
    dead("Well that was tasty!")
else:
    cthulhu_room()

def dead(why):
    print why, "Good job!"
    exit(0)

def start():
    print "You are in a dark room."
    print "There is a door to your right and left."
    print "Which one do you take?"

    next = raw_input("> ")

    if next == "left":
        bear_room()
    elif next == "right":
        cthulhu_room()
    else:
        dead("You stumble around the room until you starve.")

start()

```

# What You Should See

Here's me playing the game:

```

$ python ex35.py
You are in a dark room.
There is a door to your right and left.
Which one do you take?
> left
There is a bear here.
The bear has a bunch of honey.
The fat bear is in front of another door.
How are you going to move the bear?
> taunt bear
The bear has moved from the door. You can go through it now.
> open door
This room is full of gold. How much do you take?
> 1000
You greedy bastard! Good job!

```

# Study Drills

1. Draw a map of the game and how you flow through it.
2. Fix all of your mistakes, including spelling mistakes.
3. Write comments for the functions you do not understand. Remember doc comments?
4. Add more to the game. What can you do to both simplify and expand it.
5. The `gold_room` has a weird way of getting you to type a number. What are all the bugs in this way of doing it?

Can you make it better than just checking if "1" or "0" are in the number? Look at how `int()` works for clues.

# Common Student Questions

Help! How does this program work!?

Any time you get stuck understanding a piece of software, simply write an English comment above every line explaining what it does. As you go through doing this, correct comments that aren't right based on new information. Then when you're done try to either diagram how it works, or write a paragraph or two describing it. If you do that you'll get it.

Why are you doing `while True:`?

That makes an infinite loop.

What does `exit(0)` do?

On many operating systems a program can abort with `exit(0)`, and the number passed in will indicate an error or not. If you do `exit(1)` then it will be an error, but `exit(0)` will be a good exit. The reason it's backward from normal boolean logic (with `0==False`) is that you can use different numbers to indicate different error results. Such as you can do `exit(100)` for a different error result than `exit(2)` or `exit(1)`.

Why is `raw_input()` sometimes written as `raw_input('> ')`?

The parameter to `raw_input` is a string that it should print as a prompt before getting the user's input.

# Exercise 36: Designing and Debugging

Now that you know `if`-statements, I'm going to give you some rules for `for`-loops and `while`-loops that will keep you out of trouble. I'm also going to give you some tips on debugging so that you can figure out problems with your program. Finally, you are going to design a similar little game as in the last exercise but with a slight twist.

## Rules For If-Statements

1. Every `if`-statement must have an `else`.
2. If this `else` should never be run because it doesn't make sense, then you must use a `die` function in the `else` that prints out an error message and dies, just like we did in the last exercise. This will find *many* errors.
3. Never nest `if`-statements more than 2 deep and always try to do them 1 deep. This means if you put an `if` in an `if` then you should be looking to move that second `if` into another function.
4. Treat `if`-statements like paragraphs, where each `if`, `elif`, `else` grouping is like a set of sentences. Put blank lines before and after.
5. Your boolean tests should be simple. If they are complex, move their calculations to variables earlier in your function and use a good name for the variable.

If you follow these simple rules, you will start writing better code than most programmers. Go back to the last exercise and see if I followed all of these rules. If not, fix it.

### Warning

Never be a slave to the rules in real life. For training purposes you need to follow these rules to make your mind strong, but in real life sometimes these rules are just stupid. If you think a rule is stupid, try not using it.

## Rules For Loops

1. Use a `while`-loop only to loop forever, and that means probably never. This only applies to Python, other languages are different.
2. Use a `for`-loop for all other kinds of looping, especially if there is a fixed or limited number of things to loop over.

# Tips For Debugging

1. Do not use a "debugger". A debugger is like doing a full-body scan on a sick person. You do not get any specific useful information, and you find a whole lot of information that doesn't help and is just confusing.
2. The best way to debug a program is to use `print` to print out the values of variables at points in the program to see where they go wrong.
3. Make sure parts of your programs work as you work on them. Do not write massive files of code before you try to run them. Code a little, run a little, fix a little.

## Homework

Now write a similar game to the one that I created in the last exercise. It can be any kind of game you want in the same flavor. Spend a week on it making it as interesting as possible. For extra credit, use lists, functions, and modules (remember those from Ex. 13?) as much as possible, and find as many new pieces of Python as you can to make the game work.

There is one catch though, write up your idea for the game first. Before you start coding you must write up a map for your game. Create the rooms, monsters, and traps that the player must go through on paper before you code.

Once you have your map, try to code it up. If you find problems with the map then adjust it and make the code match.

One final word of advice: Every programmer becomes paralyzed by irrational fear starting a new large project. They then use procrastination to avoid confronting this fear and end up not getting their program working or even started. I do this. Everyone does this. The best way to avoid this is to make a list of things you should do, and then do them one at a time.

Just start doing it, do a small version, make it bigger, keep a list of things to do, and do them.

# Exercise 37: Symbol Review

It's time to review the symbols and Python words you know, and to try to pick up a few more for the next few lessons. What I've done here is written out all the Python symbols and keywords that are important to know.

In this lesson take each keyword, and first try to write out what it does from memory. Next, search online for it and see what it really does. It may be hard because some of these are going to be impossible to search for, but keep trying.

If you get one of these wrong from memory, write up an index card with the correct definition and try to "correct" your memory. If you just didn't know about it, write it down, and save it for later.

Finally, use each of these in a small Python program, or as many as you can get done. The key here is to find out what the symbol does, make sure you got it right, correct it if you do not, then use it to lock it in.

## Keywords

- and
- del
- from
- not
- while
- as
- elif
- global
- or
- with
- assert
- else
- if
- pass
- yield
- break
- except
- import
- print
- class
- exec

- `in`
- `raise`
- `continue`
- `finally`
- `is`
- `return`
- `def`
- `for`
- `lambda`
- `try`

# Data Types

For data types, write out what makes up each one. For example, with strings write out how you create a string. For numbers write out a few numbers.

- `True`
- `False`
- `None`
- `strings`
- `numbers`
- `floats`
- `lists`

# String Escapes Sequences

For string escape sequences, use them in strings to make sure they do what you think they do.

- `\\`
- `\'`
- `\"`
- `\a`
- `\b`
- `\f`
- `\n`
- `\r`
- `\t`
- `\v`

# String Formats

Same thing for string formats: use them in some strings to know what they do.

- %d
- %i
- %o
- %u
- %x
- %X
- %e
- %E
- %f
- %F
- %g
- %G
- %c
- %r
- %s
- %%

# Operators

Some of these may be unfamiliar to you, but look them up anyway. Find out what they do, and if you still can't figure it out, save it for later.

- +
- -
- \*
- \*\*
- /
- //
- %
- <
- >
- <=
- >=
- ==
- !=
- <>
- ( )
- [ ]
- { }
- @
- ,
- :
- .
- =

- ;
- +=
- -=
- \*=
- /=
- //=
- %=
- \*\*=

Spend about a week on this, but if you finish faster that's great. The point is to try to get coverage on all these symbols and make sure they are locked in your head. What's also important is to find out what you *do not* know so you can fix it later.

# Reading Code

Now go find some Python code to read. You should be reading any Python code you can and trying to steal ideas that you find. You actually should have enough knowledge to be able to read, but maybe not understand what the code does. What I'm going to teach you in this lesson is how to apply things you have learned to understand other people's code.

First, print out the code you want to understand. Yes, print it out, because your eyes and brain are more used to reading paper than computer screens. Make sure you only print a few pages at a time.

Second, go through your printout and take notes of the following:

1. Functions and what they do.
2. Where each variable is first given a value.
3. Any variables with the same names in different parts of the program. These may be trouble later.
4. Any `if`-statements without `else` clauses. Are they right?
5. Any `while`-loops that might not end.
6. Finally, any parts of code that you can't understand for whatever reason.

Third, once you have all of this marked up, try to explain it to yourself by writing comments as you go. Explain the functions, how they are used, what variables are involved, anything you can to figure this code out.

Lastly, on all of the difficult parts, trace the values of each variable line by line, function by function. In fact, do another printout and write in the margin the value of each variable that you need to "trace".

Once you have a good idea of what the code does, go back to the computer and read it again to see if you find new things. Keep finding more code and doing this until you do not need the printouts anymore.

# Study Drills

1. Find out what a "flow chart" is and write a few.
2. If you find errors in code you are reading, try to fix them and send the author your changes.

3. Another technique for when you are not using paper is to put # comments with your notes in the code. Sometimes, these could become the actual comments to help the next person.

# Common Student Questions

What's the difference between `%d` and `%i` formatting?

Shouldn't be any difference, other than people use `%d` more due to historical reasons.

How would I search for these things online?

Simply put "python" before anything you want to find. For example, to find `yield` do `python yield`.

# Exercise 38: Doing Things To Lists

You have learned about lists. When you learned about `while-loops` you "appended" numbers to the end of a list and printed them out. There was also extra credit where you were supposed to find all the other things you can do to lists in the Python documentation. That was a while back, so go find in the book where you did that and review if you do not know what I'm talking about.

Found it? Remember it? Good. When you did this you had a list, and you "called" the function `append` on it. However, you may not really understand what's going on so let's see what we can do to lists.

When you type Python code that reads `mystuff.append('hello')` you are actually setting off a chain of events inside Python to cause something to happen to the `mystuff` list. Here's how it works:

1. Python sees you mentioned `mystuff` and looks up that variable. It might have to look backwards to see if you created with `=`, look and see if it is a function argument, or maybe it's a global variable. Either way it has to find the `mystuff` first.
2. Once it finds `mystuff` it then hits the `.` (period) operator and starts to look at *variables* that are a part of `mystuff`. Since `mystuff` is a list, it knows that `mystuff` has a bunch of functions.
3. It then hits `append` and compares the name "append" to all the ones that `mystuff` says it owns. If `append` is in there (it is) then it grabs *that* to use.
4. Next Python sees the `(` (parenthesis) and realizes, "Oh hey, this should be a function." At this point it *calls* (aka runs, executes) the function just like normally, but instead it calls the function with an *extra* argument.
5. That *extra* argument is ... `mystuff`! I know, weird right? But that's how Python works so it's best to just remember it and assume that's alright. What happens then, at the end of all this is a function call that looks like:  
`append(mystuff, 'hello')` instead of what you read which is `mystuff.append('hello')`.

For the most part you do not have to know that this is going on, but it helps when you get error messages from python like this:

```
$ python
Python 2.6.5 (r265:79063, Apr 16 2010, 13:57:41)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> class Thing(object):
...     def test(hi):
...         print "hi"
...
>>> a = Thing()
>>> a.test("hello")
```

```
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
TypeError: test() takes exactly 1 argument (2 given)
>>>
```

What was all that? Well, this is me typing into the Python shell and showing you some magic. You haven't seen `class` yet but we'll get into those later. For now you see how Python said `test()` takes exactly 1 argument (2 given). If you see this it means that python changed `a.test("hello")` to `test(a, "hello")` and that somewhere someone messed up and didn't add the argument for `a`.

That might be a lot to take in, but we're going to spend a few exercises getting this concept firm in your brain. To kick things off, here's an exercise that mixes strings and lists for all kinds of fun.

```
ten_things = "Apples Oranges Crows Telephone Light Sugar"

print "Wait there's not 10 things in that list, let's fix that."

stuff = ten_things.split(' ')
more_stuff = ["Day", "Night", "Song", "Frisbee", "Corn", "Banana", "Girl", "Boy"]

while len(stuff) != 10:
    next_one = more_stuff.pop()
    print "Adding: ", next_one
    stuff.append(next_one)
    print "There's %d items now." % len(stuff)

print "There we go: ", stuff

print "Let's do some things with stuff."

print stuff[1]
print stuff[-1] # whoa! fancy
print stuff.pop()
print ' '.join(stuff) # what? cool!
print '#'.join(stuff[3:5]) # super stellar!
```

## What You Should See

```
$ python ex38.py
Wait there's not 10 things in that list, let's fix that.
Adding: Boy
There's 7 items now.
Adding: Girl
There's 8 items now.
Adding: Banana
There's 9 items now.
Adding: Corn
There's 10 items now.
There we go: ['Apples', 'Oranges', 'Crows', 'Telephone', 'Light', 'Sugar', 'Boy',
'Girl', 'Banana', 'Corn']
Let's do some things with stuff.
Oranges
Corn
Corn
Apples Oranges Crows Telephone Light Sugar Boy Girl Banana
Telephone#Light
```

# Study Drills

1. Take each function that is called, and go through the steps outlined above to translate them to what Python does. For example, `' '.join(things)` is `join(' ', things)`.
2. Translate these two ways to view the function calls in English. For example, `' '.join(things)` reads as, "Join things with ' ' between them." Meanwhile, `join(' ', things)` means, "Call join with ' ' and things." Understand how they are really the same thing.
3. Go read about "Object Oriented Programming" online. Confused? I was too. Do not worry. You will learn enough to be dangerous, and you can slowly learn more later.
4. Read up on what a "class" is in Python. *Do not read about how other languages use the word "class"*. That will only mess you up.
5. What's the relationship between `dir(something)` and the "class" of `something`?
6. If you do not have any idea what I'm talking about do not worry. Programmers like to feel smart so they invented Object Oriented Programming, named it OOP, and then used it way too much. If you think that's hard, you should try to use "functional programming".

# Common Student Questions

Didn't you say to not use **while-loops**?

Yes, so just remember sometimes you can break the rules if you have a good reason. Only idiots are slaves to rules all the time.

What does `stuff[3:5]` do?

That's getting a "slice" from the `stuff` list that is from element 3 to element 4, meaning it does *not* include element 5. It's similar to how `range(3,5)` would work.

Why does `join(' ', stuff)` not work?

The way the documentation for `join` is written doesn't make sense. It does not work like that, and is instead a method you call on the *inserted* string to put between the list to be joined. Rewrite it like `' '.join(stuff)`.

# Exercise 39: Dictionaries, Oh Lovely Dictionaries

Now I have to hurt you with another container you can use, because once you learn this container a massive world of ultra-cool will be yours. It is the most useful container ever: the dictionary.

Python calls them "dicts", other languages call them, "hashes". I tend to use both names, but it doesn't matter. What does matter is what they do when compared to lists. You see, a list lets you do this:

```
>>> things = ['a', 'b', 'c', 'd']
>>> print things[1]
b
>>> things[1] = 'z'
>>> print things[1]
z
>>> print things
['a', 'z', 'c', 'd']
>>>
```

You can use numbers to "index" into a list, meaning you can use numbers to find out what's in lists. You should know this about lists by now, but make sure you understand that you can *only* use numbers to get items out of a list.

What a dict does is let you use *anything*, not just numbers. Yes, a dict associates one thing to another, no matter what it is. Take a look:

```
>>> stuff = {'name': 'Zed', 'age': 36, 'height': 6*12+2}
>>> print stuff['name']
Zed
>>> print stuff['age']
36
>>> print stuff['height']
74
>>> stuff['city'] = "San Francisco"
>>> print stuff['city']
San Francisco
>>>
```

You will see that instead of just numbers we're using strings to say what we want from the `stuff` dictionary. We can also put new things into the dictionary with strings. It doesn't have to be strings though, we can also do this:

```
>>> stuff[1] = "Wow"
>>> stuff[2] = "Neato"
>>> print stuff[1]
```

```
Wow
>>> print stuff[2]
Neato
>>> print stuff
{'city': 'San Francisco', 2: 'Neato',
 'name': 'Zed', 1: 'Wow', 'age': 36,
 'height': 74}
>>>
```

In this code I used numbers, and then you can see there's numbers and strings as keys in the dict when I print it. I could use anything. Well almost but just pretend you can use anything for now.

Of course, a dictionary that you can only put things in is pretty stupid, so here's how you delete things, with the `del` keyword:

```
>>> del stuff['city']
>>> del stuff[1]
>>> del stuff[2]
>>> stuff
{'name': 'Zed', 'age': 36, 'height': 74}
>>>
```

We'll now do an exercise that you *must* study very carefully. I want you to type this exercise in and try to understand what's going on. Take note of when I put things in a dict, get from them, and all the operations I use here.

```
# create a mapping of state to abbreviation
states = {
    'Oregon': 'OR',
    'Florida': 'FL',
    'California': 'CA',
    'New York': 'NY',
    'Michigan': 'MI'
}

# create a basic set of states and some cities in them
cities = {
    'CA': 'San Francisco',
    'MI': 'Detroit',
    'FL': 'Jacksonville'
}

# add some more cities
cities['NY'] = 'New York'
cities['OR'] = 'Portland'

# print out some cities
print '-' * 10
print "NY State has: ", cities['NY']
print "OR State has: ", cities['OR']

# print some states
print '-' * 10
print "Michigan's abbreviation is: ", states['Michigan']
print "Florida's abbreviation is: ", states['Florida']

# do it by using the state then cities dict
print '-' * 10
print "Michigan has: ", cities[states['Michigan']]
print "Florida has: ", cities[states['Florida']]

# print every state abbreviation
```

```

print '-' * 10
for state, abbrev in states.items():
    print "%s is abbreviated %s" % (state, abbrev)

# print every city in state
print '-' * 10
for abbrev, city in cities.items():
    print "%s has the city %s" % (abbrev, city)

# now do both at the same time
print '-' * 10
for state, abbrev in states.items():
    print "%s state is abbreviated %s and has city %s" % (
        state, abbrev, cities[abbrev])

print '-' * 10
# safely get a abbreviation by state that might not be there
state = states.get('Texas', None)

if not state:
    print "Sorry, no Texas."

# get a city with a default value
city = cities.get('TX', 'Does Not Exist')
print "The city for the state 'TX' is: %s" % city

```

# What You Should See

```

$ python ex39.py
-----
NY State has:  New York
OR State has:  Portland
-----
Michigan's abbreviation is:  MI
Florida's abbreviation is:  FL
-----
Michigan has:  Detroit
Florida has:  Jacksonville
-----
California is abbreviated CA
Michigan is abbreviated MI
New York is abbreviated NY
Florida is abbreviated FL
Oregon is abbreviated OR
-----
FL has the city Jacksonville
CA has the city San Francisco
MI has the city Detroit
OR has the city Portland
NY has the city New York
-----
California state is abbreviated CA and has city San Francisco

```

```
Michigan state is abbreviated MI and has city Detroit
New York state is abbreviated NY and has city New York
Florida state is abbreviated FL and has city Jacksonville
Oregon state is abbreviated OR and has city Portland
-----
Sorry, no Texas.
The city for the state 'TX' is: Does Not Exist
```

# Study Drills

1. Do this same kind of mapping with cities and states/regions in your country, or or some other country.
2. Go find the Python documentation for dictionaries (a.k.a. `dicts`, `dict`) and try to do even more things to them.
3. Find out what you *can't* do with dictionaries. A big one is that they do not have order, so try playing with that.

# Common Student Questions

What is the difference between a list and a dictionary?

A list is for an ordered list of items. A dictionary (or `dict`) is for matching some items (called "keys") to other items (called "values").

What would I use a dictionary for?

Any time you have to take one value, and "look up" another value. In fact you could call dictionaries "look up tables".

What would I use a list for?

A list is for any sequence of things that need to go in order, and you only need to look them up by a numeric index.

What if I need a dictionary, but I need it to be in order?

Take a look at the `collections.OrderedDict` data structure in Python. Search for it online to find the documentation.

# Exercise 40: Modules, Classes, And Objects

Python is something called an "Object Oriented Programming Language". What this means is there's a construct in Python called a *class* that lets you structure your software in a particular way. Using classes you can add consistency to your programs so that they can be used in a cleaner way, or at least that's the theory.

I am now going to try to teach you the beginnings of Object Oriented Programming, classes, and objects using what you already know about dictionaries and modules. My problem though is that Object Oriented Programming (aka OOP) is just plain weird. You have to simply struggle with this, try to understand what I say here, type in the code, and then in the next exercise I'll hammer it in.

Here we go.

## Modules Are Like Dictionaries

You know how a dictionary is created and used, and that it is a way to map one thing to another. That means if you have a dictionary with a key 'apple' and you want to get it then you do this:

```
mystuff = {'apple': "I AM APPLES!"}
print mystuff['apple']
```

Keep this idea of "get X from Y" in your head, and now think about modules. You've made a few so far, and used them, and you know they are:

1. A Python file with some functions or variables in it.
2. You then import that file.
3. And then you can access the functions or variables in that module with the '.' (dot) operator.

Imagine if I have a module that I decide to name *mystuff.py* and I put a function in it called *apple*. Here's the module *mystuff.py*:

```
# this goes in mystuff.py
def apple():
    print "I AM APPLES!"
```

Once I have that, I can use that module with *import* and then access the *apple* function:

```
import mystuff

mystuff.apple()
```

I could also put a variable in it named *tangerine* like this:

```
def apple():
    print "I AM APPLES!"

# this is just a variable
tangerine = "Living reflection of a dream"
```

Then again I can access that the same way:

```
import mystuff

mystuff.apple()
print mystuff.tangerine
```

Go refer back to the dictionary, and you should start to see how this is similar to using a dictionary, but the syntax is different. Let's compare:

```
mystuff['apple'] # get apple from dict
mystuff.apple() # get apple from the module
mystuff.tangerine # same thing, it's just a variable
```

This means we have a very common pattern in Python of this:

1. Take a key=value style container.
2. Get something out of it by the key's name.

In the case of the dictionary, the key is a string and the syntax is *[key]*. In the case of the module, the key is an identifier, and the syntax is *.key*. Other than that they are nearly the same thing.

# Classes Are Like Modules

A way to think about modules is they are a specialized dictionary that can store Python code so you can get to it with the *'* operator. Python also has another construct that serves a similar purpose called a *class*. A *class* is a way to take a grouping of functions and data and place them inside a container so you can access them with the *'* (dot) operator.

If I were to create a class just like the *mystuff* module, I'd do something like this:

```
class MyStuff(object):

    def __init__(self):
        self.tangerine = "And now a thousand years between"
```

```
def apple(self):
    print "I AM CLASSY APPLES!"
```

That looks complicated compared to modules, and there is definitely a lot going on by comparison, but you should be able to make out how this is like a "mini-module" with *MyStuff* having an *apple()* function in it. What is probably confusing with this is the `__init__()` function and use of *self.tangerine* for setting the *tangerine* variable.

Here's why classes are used instead of modules: You can take the above class, and use it to craft many of them, millions at a time if you want, and they won't interfere with each other. With modules, when you import there is only one for the entire program unless you do some monster hacks.

Before you can understand this though, you need to know what an "object" is and how to work with *MyStuff* just like you do with the *mystuff.py* module.

## Objects Are Like Mini Imports

If a *class* is like a "mini-module", then there has to be a similar concept to *import* but for classes. That concept is called "instantiate" which is just a fancy obnoxious overly smart way to say "create". When you instantiate a class, what you get is called an *object*.

The way you do this is you call the *class* like it's a function, like this:

```
thing = MyStuff()
thing.apple()
print thing.tangerine
```

The first line is the "instantiate" operation, and it's a lot like calling a function. However, when you call this there's a sequence of events that Python coordinates for you. I'll go through them using the above code for *MyStuff*:

1. Python looks for *MyStuff()* and sees that it is a *class* you've defined.
2. Python crafts an empty object with all the functions you've specified in the class using *def*.
3. Python then looks to see if you made a "magic" `__init__` function, and if you have it calls that function to initialize your newly created empty object.
4. In the *MyStuff* function `__init__` I then get this extra variable *self* which is that empty object Python made for me, and I can set variables on it just like you would with a module, dict, or other object.
5. In this case, I set *self.tangerine* to a song lyric and then I've initialized this object.
6. Now Python can take this newly minted object, and assign it to the *thing* variable for me to work with.

That's the basics of how Python does this "mini-import" when you call a *class* like a function. Remember that this is *not* giving you the class, but instead it is using the class as a *blueprint* for how to build a copy of that type of thing.

Keep in mind that I'm giving you a slightly inaccurate idea for how these work so that you can start to build up an understanding of classes based on what you know of modules. The truth is, classes and objects suddenly diverge from modules at this point. If I were being totally honest, I'd say something more like this:

- Classes are like blueprints or definitions for creating new mini-modules.

- Instantiation is how you make one of these mini-modules *and* import it at the same time.
- The resulting created mini-module is called an *object* and you then assign it to a variable to work with it.

After this though classes and objects become very different from modules and this should only serve as a way for you to bridge over to understanding classes.

# Getting Things From Things

I now have three ways to "get things from things":

```
# dict style
mystuff['apples']

# module style
mystuff.apples()
print mystuff.tangerine

# class style
thing = MyStuff()
thing.apples()
print thing.tangerine
```

## A First Class Example

You should start seeing the similarities in these three key=value container types and probably have a bunch of questions. Hang on with the questions, as the next exercise is going to hammer home your "object oriented vocabulary". In this exercise, I just want you to type in this code and get it working so that you have some experience before moving on.

```
class Song(object):

    def __init__(self, lyrics):
        self.lyrics = lyrics

    def sing_me_a_song(self):
        for line in self.lyrics:
            print line

happy_bday = Song(["Happy birthday to you",
                  "I don't want to get sued",
                  "So I'll stop right there"])

bulls_on_parade = Song(["They rally around the family",
                       "With pockets full of shells"])

happy_bday.sing_me_a_song()

bulls_on_parade.sing_me_a_song()
```

## What You Should See

```
$ python ex40.py
Happy birthday to you
```

```
I don't want to get sued  
So I'll stop right there  
They rally around the family  
With pockets full of shells
```

# Study Drills

1. Write some more songs using this, make sure you understand that you're passing a list of strings as the lyrics.
2. Put the lyrics in a separate variable, then pass that variable to the class to use instead.
3. See if you can hack on this and make it do more things. Don't worry if you have no idea how, just give it a try, see what happens. Break it, trash it, thrash it, you can't hurt it.
4. Search online for "object oriented programming" and try to overflow your brain with what you read. Don't worry if it makes absolutely no sense to you. Half of that stuff makes no sense to me too.

# Common Student Questions

Why do I need **self** when I make `__init__` or other functions for classes?

If you don't have `self`, then code like `cheese = 'Frank'` is ambiguous. That code isn't clear about whether you mean the *instance's* `cheese` attribute, or a local variable named `cheese`. With `self.cheese = 'Frank'` it's very clear you mean the instance attribute `self.cheese`.

# Exercise 41: Learning To Speak Object Oriented

In this exercise I'm going to teach you how to speak "object oriented". What I'll do is give you a small set of words with definitions you need to know. Then I'll give you a set of sentences with holes in them that you'll have to understand. Finally, I'm going to give you a large set of exercises that you have to complete to make these sentences solid in your vocabulary.

## Word Drills

- **class** : Tell Python to make a new kind of thing.
- **object** : Two meanings: the most basic kind of thing, and any instance of some thing.
- **instance** : What you get when you tell Python to create a class.
- **def** : How you define a function inside a class.
- **self** : Inside the functions in a class, self is a variable for the instance/object being accessed.
- **inheritance** : The concept that one class can inherit traits from another class, much like you and your parents.
- **composition** : The concept that a class can be composed of other classes as parts, much like how a car has wheels.
- **attribute** : A property classes have that are from composition and are usually variables.
- **is-a** : A phrase to say that something inherits from another, as in a Salmon is-a Fish.
- **has-a** : A phrase to say that something is composed of other things or has a trait, as in a Salmon has-a mouth.

Alright, take some time to make flash cards for those and memorize them. As usual this won't make too much sense until after you're done with this exercise, but you need to know the base words first.

## Phrase Drills

Next I have a list of Python code snippets on the left, and the English sentences for them:

```
class X(Y)
```

"Make a class named X that is-a Y."

```
class X(object): def __init__(self, J)
```

"class X has-a \_\_init\_\_ that takes self and J parameters."

```
class X(object): def M(self, J)
```

"class X has-a function named M that takes self and J parameters."

```
foo = X()
    "Set foo to an instance of class X."

foo.M(J)
    "From foo get the M function, and call it with parameters self, J."

foo.K = Q
    "From foo get the K attribute and set it to Q."
```

In each of these where you see X, Y, M, J, K, Q, and foo you can treat those like blank spots. For example I can also write these sentences as:

1. "Make a class named ??? that is-a Y."
2. "class ??? has-a \_\_init\_\_ that takes self and ??? parameters."
3. "class ??? has-a function named ??? that takes self and ??? parameters."
4. "Set foo to an instance of class ???."
5. "From foo get the ??? function, and call it with self=??? and parameters ???."
6. "From foo get the ??? attribute and set it to ???."

Again, write these on some flash cards and drill them. Put the Python code snippet on the front and the sentence on the back. You *have* to be able to say the sentence exactly the same every time whenever you see that form. Not sort of the same, but exactly the same.

## Combined Drills

The final preparation for you is to combine the words drills with the phrase drills. What I want you to do for this drill is this:

1. Take a phrase card and drill it.
2. Flip it over and read the sentence, and for each word in the sentence that is in your words drills, get that card.
3. Drill those words for that sentence.
4. Keep going until you are bored then take a break and do it again.

## A Reading Test

I now have a little Python hack that will drill you on these words you know in an infinite manner. This is a simple script you should be able to figure out, and the only thing it does is use a library called *urllib* to download a list of words I have. Here's the script, which you should enter into *oop\_test.py* to work with it:

```
import random
from urllib import urlopen
import sys

WORD_URL = "http://learncodethehardway.org/words.txt"
WORDS = []
```

```

PHRASES = {
    "class ###(###)": "Make a class named ### that is-a ###.",
    "class ###(object):\n\tdef __init__(self, ***)" :
        "class ### has-a __init__ that takes self and *** parameters.",
    "class ###(object):\n\tdef ***(self, @@@)":
        "class ### has-a function named *** that takes self and @@@ parameters.",
    "*** = ###()":
        "Set *** to an instance of class ###.",
    "***.***(@@@)":
        "From *** get the *** function, and call it with parameters self, @@@.",
    "***.*** = '***'":
        "From *** get the *** attribute and set it to '***'."
}

# do they want to drill phrases first
PHRASE_FIRST = False
if len(sys.argv) == 2 and sys.argv[1] == "english":
    PHRASE_FIRST = True

# load up the words from the website
for word in urlopen(WORD_URL).readlines():
    WORDS.append(word.strip())

def convert(snippet, phrase):
    class_names = [w.capitalize() for w in
                    random.sample(WORDS, snippet.count("###"))]
    other_names = random.sample(WORDS, snippet.count("***"))
    results = []
    param_names = []

    for i in range(0, snippet.count("@@@")):
        param_count = random.randint(1,3)
        param_names.append(', '.join(random.sample(WORDS, param_count)))

    for sentence in snippet, phrase:
        result = sentence[:]

        # fake class names
        for word in class_names:
            result = result.replace("###", word, 1)

        # fake other names
        for word in other_names:
            result = result.replace("***", word, 1)

        # fake parameter lists
        for word in param_names:
            result = result.replace("@@@", word, 1)

        results.append(result)

    return results

# keep going until they hit CTRL-D
try:
    while True:
        snippets = PHRASES.keys()
        random.shuffle(snippets)

        for snippet in snippets:
            phrase = PHRASES[snippet]
            question, answer = convert(snippet, phrase)
            if PHRASE_FIRST:
                question, answer = answer, question

            print question

```

```
raw_input( "> " )
print "ANSWER:  %s\n\n" % answer
except EOFError:
    print "\nBye"
```

Run this script and try to translate the "Object Oriented Phrases" into English translations. You should see that the PHRASES dict has both forms and you just have to enter the correct one.

# Practice English To Code

Next you should run the script with the "english" option so that you drill the inverse operation.

Remember that these phrases are using nonsense words. Part of learning to read code well is to stop placing so much meaning on the names used for variables and classes. Too often people will read a word like "Cork" and suddenly get derailed because that word will confuse them about the meaning. In the above example, "Cork" is just an arbitrary name chosen for a class. Don't put any other meaning into it, and instead treat it like the patterns I've given you.

# Reading More Code

You are now to go on a new quest to read even more code and this time, to read the phrases you just learned in the code you read. You will look for all the files with classes, and then do the following:

1. For each class give its name and what other classes it inherits from.
2. Under that, list every function it has, and the parameters they take.
3. List all of the attributes it uses on self.
4. For each attribute, give the class it is.

The goal is to go through real code and start learning to "pattern match" the phrases you just learned against how they're used. If you drill this enough you should start to see these patterns shout at you in the code whereas before they just seemed like vague blank spots you didn't know.

# Common Student Questions

What does `result = sentence[:]` do?

That's a Python way of copying a list. You're using the list slice syntax `[ : ]` to effectively make a slice from the very first element to the very last one.

This script is hard to get running!

By this point you should be able to type this in and get it working. It does have a few little tricks here and there but there's nothing complex about it. Just do all the things you've learned so far to debug scripts like this.

# Exercise 42: Is-A, Has-A, Objects, and Classes

An important concept that you have to understand is the difference between a `Class` and an `Object`. The problem is, there is no real "difference" between a class and an object. They are actually the same thing at different points in time. I will demonstrate by a Zen koan:

What is the difference between a Fish and a Salmon?

Did that question sort of confuse you? Really sit down and think about it for a minute. I mean, a Fish and a Salmon are different but, wait, they are the same thing right? A Salmon is a *kind* of Fish, so I mean it's not different. But at the same time, because a Salmon is a particular *type* of Fish and so it's actually different from all other Fish. That's what makes it a Salmon and not a Halibut. So a Salmon and a Fish are the same but different. Weird.

This question is confusing because most people do not think about real things this way, but they intuitively understand them. You do not need to think about the difference between a Fish and a Salmon because you *know* how they are related. You know a Salmon is a *kind* of Fish and that there are other kinds of Fish without having to understand that.

Let's take it one step further, let's say you have a bucket full of 3 Salmon and because you are a nice person, you have decided to name them Frank, Joe, and Mary. Now, think about this question:

What is the difference between Mary and a Salmon?

Again this is a weird question, but it's a bit easier than the Fish vs. Salmon question. You know that Mary is a Salmon, and so she's not really different. She's just a specific "instance" of a Salmon. Joe and Frank are also instances of Salmon. But, what do I mean when I say instance? I mean they were created from some other Salmon and now represent a real thing that has Salmon-like attributes.

Now for the mind bending idea: Fish is a `Class`, and Salmon is a `Class`, and Mary is an `Object`. Think about that for a second. Alright let's break it down real slow and see if you get it.

A Fish is a `Class`, meaning it's not a *real* thing, but rather a word we attach to instances of things with similar attributes. Got fins? Got gills? Lives in water? Alright it's probably a Fish.

Someone with a Ph.D. then comes along and says, "No my young friend, *this* Fish is actually *Salmo salar*, affectionately known as a Salmon." This professor has just clarified the Fish further and made a new `Class` called "Salmon" that has more specific attributes. Longer nose, reddish flesh, big, lives in the ocean or fresh water, tasty? Ok, probably a Salmon.

Finally, a cook comes along and tells the Ph.D., "No, you see this Salmon right here, I'll call her Mary and I'm going to make a tasty fillet out of her with a nice sauce." Now you have this *instance* of a Salmon (which also is an instance of a Fish) named Mary turned into something real that is filling your belly. It has become an `Object`.

There you have it: Mary is a kind of Salmon that is a kind of Fish. `Object` is a `Class` is a `Class`.

# How This Looks In Code

This is a weird concept, but to be very honest you only have to worry about it when you make new classes, and when you use a class. I will show you two tricks to help you figure out whether something is a `Class` or `Object`.

First, you need to learn two catch phrases "is-a" and "has-a". You use the phrase is-a when you talk about objects and classes being related to each other by a class relationship. You use has-a when you talk about objects and classes that are related only because they *reference* each other.

Now, go through this piece of code and replace each `##??` comment with a replacement comment that says whether the next line represents an is-a or a has-a relationship, and what that relationship is. In the beginning of the code, I've laid out a few examples, so you just have to write the remaining ones.

Remember, is-a is the relationship between Fish and Salmon, while has-a is the relationship between Salmon and Gills.

```
## Animal is-a object (yes, sort of confusing) look at the extra credit
```

```
class Animal(object):  
    pass
```

```
## ??  
class Dog(Animal):
```

```
    def __init__(self, name):  
        ## ??  
        self.name = name
```

```
## ??  
class Cat(Animal):
```

```
    def __init__(self, name):  
        ## ??  
        self.name = name
```

```
## ??  
class Person(object):
```

```
    def __init__(self, name):  
        ## ??  
        self.name = name  
  
        ## Person has-a pet of some kind  
        self.pet = None
```

```
## ??  
class Employee(Person):
```

```
    def __init__(self, name, salary):  
        ## ?? hmm what is this strange magic?  
        super(Employee, self).__init__(name)  
        ## ??  
        self.salary = salary
```

```

## ??
class Fish(object):
    pass

## ??
class Salmon(Fish):
    pass

## ??
class Halibut(Fish):
    pass

## rover is-a Dog
rover = Dog("Rover")

## ??
satan = Cat("Satan")

## ??
mary = Person("Mary")

## ??
mary.pet = satan

## ??
frank = Employee("Frank", 120000)

## ??
frank.pet = rover

## ??
flipper = Fish()

## ??
crouse = Salmon()

## ??
harry = Halibut()

```

# About class Name(object)

Remember how I was yelling at you to always use `class Name(object)` and I couldn't tell you why? Now I can tell you, because you just learned about the difference between a `class` and an `object`. I couldn't tell you until now because you would have just been confused and couldn't learn to use the technology.

What happened is Python's original rendition of `class` was broken in many serious ways. By the time they admitted the fault it was too late, and they had to support it. In order to fix the problem, they needed some "new class" style so that the "old classes" would keep working but you could use the new more correct version.

This is where "class is-a object" comes in. They decided that they would use the word "object", lowercased, to be the "class" that you inherit from to make a class. Confusing right? A class inherits from the class named `object` to make a class but it's not an object really it's a class, but do not forget to inherit from `object`.

Exactly. The choice of one single word meant that I couldn't teach you about this until now. Now you can try to understand the concept of a class that is an object if you like.

However, I would suggest you do not. Just completely ignore the idea of old style vs. new style classes and assume that Python always requires (object) when you make a class. Save your brain power for something important.

# Study Drills

1. Research why Python added this strange `object` class, and what that means.
2. Is it possible to use a `Class` like it's an `Object`?
3. Fill out the animals, fish, and people in this exercise with functions that make them do things. See what happens when functions are in a "base class" like `Animal` vs. in say `Dog`.
4. Find other people's code and work out all the is-a and has-a relationships.
5. Make some new relationships that are lists and dicts so you can also have "has-many" relationships.
6. Do you think there's a such thing as a "is-many" relationship? Read about "multiple inheritance", then avoid it if you can.

# Common Student Questions

What are these `## ??` comments for?

Those are "fill-in-the-blank" comments that you are supposed to fill in with the right "is-a", "has-a" concepts. Re-read this exercise and look at the other comments to see what I mean.

What is the point of `self.pet = None`?

That makes sure that the `self.pet` attribute of that class is set to a default of `None`.

What does `super(Employee, self).__init__(name)` do?

That's how you can run the `__init__` method of a parent class reliably. Go search for "python super" and read the various advice on it being evil and good for you.

# Exercise 43: Basic Object Oriented Analysis And Design

I'm going to describe a process to use when you want to build something using Python, and specifically with Object Oriented Programming (OOP). What I mean by a "process" is that I'll give you a set of steps that you do in order, but that you aren't meant to be a slave to or that will totally always work for every problem. They are just a good starting point for many programming problems and shouldn't be considered the *only* way to solve these type of problems. This process is just one way to do it that you can follow.

The process is as follows:

1. Write or draw about the problem.
2. Extract key concepts from #1 and research them.
3. Create a class hierarchy and object map for the concepts.
4. Code the classes and a test to run them.
5. Repeat and refine.

The way to look at this process is that it is "top down", meaning it starts from the very abstract loose idea and then slowly refines it until the idea is solid and something you can code.

First I start by just writing about the problem and trying to think up anything I can about it. Maybe I'll even draw a diagram or two, maybe a map of some kind, or even write myself a series of emails describing the problem. This gives me a way to express the key concepts in the problem and also explore what I might already know about it.

Then I go through these notes, drawings, and descriptions and I pull out the key concepts. There's a simple trick to doing this: Simply make a list of all the *nouns* and *verbs* in your writing and drawings, then write out how they're related. This gives me a good list of names for classes, objects, and functions in the next step. I take this list of concepts and then research any that I don't understand so I can refine them further if I need.

Once I have my list of concepts I create a simple outline/tree of the concepts and how they are related as classes. You can usually take your list of noun and start asking "Is this one like other concept nouns? That means they have a common subclass, so what is it called?" Keep doing this until you have a class hierarchy that's just a simple tree list or a diagram. Then take the *verbs* you have and see if those are function names for each class and put them in your tree.

With this class hierarchy figured out, I sit down and write some basic skeleton code that has just the classes, their functions, and nothing more. I then write a test that runs this code and makes sure the classes I've made make sense and work right. Sometimes I may write the test first though, and other times I might write a little test, a little code, a little

test, etc. until I have the whole thing built.

Finally, I keep cycling over this process repeating it and refining as I go making it as clear as I can before doing more implementation. If I get stuck at any particular part because of a concept or problem I haven't anticipated, then I sit down and start the process over on just that part to figure it out more before continuing.

I will now go through this process while coming up with a game engine and a game for this exercise.

# The Analysis Of A Simple Game Engine

The game I want to make is called "Gothons From Planet Percal #25" and will be a small space battles game. I don't have much more in my mind other than that so it's time to explore and figure out how to make the game come to life.

## Write Or Draw About The Problem

I suck at drawing, so I'm going to write a little paragraph for the game:

```
Aliens have invaded a space ship and our hero has to go through a maze of
rooms defeating them so he can escape into an escape pod to the planet
below. The game will be more like a Zork or Adventure type game with text
outputs and funny ways to die. The game will involve an engine that runs a
map full of rooms or scenes. Each room will print its own description
when the player enters it and then tell the engine what room to run
next out of the map.
```

At this point I have a good idea for the game and how it would run, so now I want to describe each scene:

### Death

This is when the player dies and should be something funny.

### Central Corridor

This is the starting point and has a Gothon already standing there they have to defeat with a joke before continuing.

### Laser Weapon Armory

This is where the hero gets a neutron bomb to blow up the ship before getting to the escape pod. It has a keypad he has to guess the number for.

### The Bridge

Another battle scene with a Gothon where the hero places the bomb.

### Escape Pod

Where the hero escapes but only after guessing the right escape pod.

At this point I might draw out a map of these, maybe write more descriptions of each room, whatever comes to mind as I explore the problem.

# Extract Key Concepts And Research Them

I now have enough information to extract some of the nouns out and analyze their class hierarchy. First I make a list of all the nouns:

- Alien
- Player
- Ship
- Maze
- Room
- Scene
- Gothon
- Escape Pod
- Planet
- Map
- Engine
- Death
- Central Corridor
- Laser Weapon Armory
- The Bridge

I would also possibly go through all the verbs and see if they are anything that might be good function names, but I'll skip that for now.

At this point you might also research each of these concepts and anything you don't know right now. For example, I might play a few of these style of games and make sure I know how they work. I might go research how ships are designed or how bombs work. Maybe I'll go research some technical issue like how to store the game's state in a database. After I've done this research I might start over at step #1 based on new information I have and rewrite my description and extract new concepts.

## Create A Class Hierarchy And Object Map For The Concepts

Once I have that I turn it into a class hierarchy by asking "What is similar to other things?" I also ask "What is basically just another word for another thing?"

Right away I see that I can say "Room" and "Scene" are basically the same thing depending on how I want to do things. I'm going to pick "Scene" for this game. Then I see that all the specific rooms like "Central Corridor" are basically just Scenes. I see also that Death is basically a Scene, which confirms my choice of "Scene" over "Room" since you can have a death scene, but a death room is kind of odd. "Maze" and "Map" are basically the same so I'm going to go with "Map" since I used it more often. I don't want to do a battle system so I'm going to ignore "Alien" and "Player" and save

that for later. And the "Planet" could also just be another scene instead of something specific.

After all of that thought process I start to make a class hierarchy that looks like this in my text editor:

```
* Map
* Engine
* Scene
  * Death
  * Central Corridor
  * Laser Weapon Armory
  * The Bridge
  * Escape Pod
```

I would also then go through and figure out what actions are needed on each thing based on verbs in the description. For example, I know that from the above description I'm going to need a way to "run" the engine, "get the next scene" from the map, getting the "opening scene", and "enter" a scene. I'll add those like this:

```
* Map
  - next_scene
  - opening_scene
* Engine
  - play
* Scene
  - enter
  * Death
  * Central Corridor
  * Laser Weapon Armory
  * The Bridge
  * Escape Pod
```

Notice how I just put `-enter` under `Scene` since I know that all the scenes under it will inherit it and have to override it later.

## Code The Classes And A Test To Run Them

Once I have this tree of classes and some of the functions I open up a source file in my editor and try to write the code for it. Usually I'll just copy-paste the above tree into the source file and then edit it into classes. Here's a small example of how this might look at first, with a simple little test at the end of the file.

```
class Scene(object):

    def enter(self):
        pass

class Engine(object):

    def __init__(self, scene_map):
        pass

    def play(self):
        pass
```

```
class Death(Scene):
    def enter(self):
        pass

class CentralCorridor(Scene):
    def enter(self):
        pass

class LaserWeaponArmory(Scene):
    def enter(self):
        pass

class TheBridge(Scene):
    def enter(self):
        pass

class EscapePod(Scene):
    def enter(self):
        pass

class Map(object):
    def __init__(self, start_scene):
        pass

    def next_scene(self, scene_name):
        pass

    def opening_scene(self):
        pass

a_map = Map('central_corridor')
a_game = Engine(a_map)
a_game.play()
```

In this file you can see that I simply replicated the hierarchy I wanted and then a little bit of code at the end to run it and see if it all works in this basic structure. In the later sections of this exercise you'll fill in the rest of this code and make it work to match the description of the game.

## Repeat And Refine

The last step in my little process isn't so much a step as it is a while-loop. You don't ever do this as a one pass operation. Instead you go back over the whole process again and refine it based on information you've learned from later steps. Sometimes I'll get to step #3 and realize that I need to work on #1 and #2 more, so I'll stop and go back and work on those. Sometimes I'll get a flash of inspiration and jump to the end to code up the solution in my head while I have it there, but then I'll go back and do the previous steps to make sure I cover all the possibilities I have.

The other idea in this process is that it's not just something you do at one single level, but something that you can do at every level when you run into a particular problem. Let's say I don't know how to write the `Engine.play` method yet. Well I can stop and do this whole process on *just* that one function to figure out how to write it.

# Top Down vs. Bottom Up

The process I just described is typically labeled "top down" since it starts at the most abstract concepts (the top) and works its way down to actual implementation. I want you to use this process I just described when analyzing problems in the book from now on, but you should know that there's another way to solve problems in programming that starts with code and goes "up" to the abstract concepts. This other way is labeled "bottom up". Here's the general steps you follow to do this:

1. Take a small piece of the problem, hack on some code and get it to run barely.
2. Refine the code into something more formal with classes and automated tests.
3. Extract the key concepts you're using and try to find research for them.
4. Write up a description of what's really going on.
5. Go back and refine the code, possibly throwing it out and starting over.
6. Repeat, moving on to some other piece of the problem.

This process I find is better once you're more solid at programming and are naturally thinking in code about problems. This process is very good when you know small pieces of the overall puzzle, but maybe don't have enough information yet about the overall concept. Breaking it down in little pieces and exploring with code then helps you slowly grind away at the problem until you've solved it. However, remember that your solution will probably be meandering and weird, so that's why my version of this process involves going back and finding research then cleaning things up based on what you've learned.

## The Code For "Gothons From Planet Percal #25"

Stop! I'm going to show you my final solution to the above problem but I don't want you to just jump in and type this up. I want *you* to take the rough skeleton code I did above and then try to make it work based on the description. Once you have your solution then you can come back and see how I did it.

I'm going to break this final file `ex43.py` down into sections and explain each one rather than dump all the code at once.

```
from sys import exit
from random import randint
```

This is just our basic imports for the game, nothing fancy really.

```
class Scene(object):

    def enter(self):
        print "This scene is not yet configured. Subclass it and implement enter()."
        exit(1)
```

As you saw in the skeleton code, I have a base class for `Scene` that will have the common things that all scenes do. In this simple program they don't do much so this is more a demonstration of what you would do to make a base class.

```
class Engine(object):

    def __init__(self, scene_map):
        self.scene_map = scene_map

    def play(self):
        current_scene = self.scene_map.opening_scene()

        while True:
            print "\n-----"
            next_scene_name = current_scene.enter()
            current_scene = self.scene_map.next_scene(next_scene_name)
```

I also have my `Engine` class and you can see how I'm already just using the methods for `Map.opening_scene` and `Map.next_scene`. Because I've done a bit of planning I can just assume I'll write those and then use them before I've written the `Map` class.

```
class Death(Scene):

    quips = [
        "You died.  You kinda suck at this.",
        "Your mom would be proud...if she were smarter.",
        "Such a luser.",
        "I have a small puppy that's better at this."
    ]

    def enter(self):
        print Death.quips[randint(0, len(self.quips)-1)]
        exit(1)
```

My first scene is the odd scene named `Death` which shows you the simplest kind of scene you can write.

```
class CentralCorridor(Scene):

    def enter(self):
        print "The Gothons of Planet Percal #25 have invaded your ship and destroyed"
        print "your entire crew.  You are the last surviving member and your last"
        print "mission is to get the neutron destruct bomb from the Weapons Armory,"
        print "put it in the bridge, and blow the ship up after getting into an "
        print "escape pod."
        print "\n"
        print "You're running down the central corridor to the Weapons Armory when"
        print "a Gothon jumps out, red scaly skin, dark grimy teeth, and evil clown"
        print "costume"
        print "flowing around his hate filled body.  He's blocking the door to the"
        print "Armory and about to pull a weapon to blast you."

        action = raw_input("> ")

        if action == "shoot!":
            print "Quick on the draw you yank out your blaster and fire it at the"
            print "Gothon."
            print "His clown costume is flowing and moving around his body, which"
            print "throws"
            print "off your aim.  Your laser hits his costume but misses him entirely."
            print "This"
            print "completely ruins his brand new costume his mother bought him, which"
            print "makes him fly into an insane rage and blast you repeatedly in the
```

```

face until"
    print "you are dead.  Then he eats you."
    return 'death'

elif action == "dodge!":
    print "Like a world class boxer you dodge, weave, slip and slide right"
    print "as the Gothons' blaster cranks a laser past your head."
    print "In the middle of your artful dodge your foot slips and you"
    print "bang your head on the metal wall and pass out."
    print "You wake up shortly after only to die as the Gothons stomp on"
    print "your head and eats you."
    return 'death'

elif action == "tell a joke":
    print "Lucky for you they made you learn Gothon insults in the academy."
    print "You tell the one Gothon joke you know:"
    print "Lbhe zbgure vf fb sng, jura fur fvgf nebhaq gur ubhfr, fur fvgf"
    print "The Gothon stops, tries not to laugh, then busts out laughing and"
    print "While he's laughing you run up and shoot him square in the head"
    print "putting him down, then jump through the Weapon Armory door."
    return 'laser_weapon_armory'

else:
    print "DOES NOT COMPUTE!"
    return 'central_corridor'

```

After that I've created the CentralCorridor which is the start of the game. I'm doing the scenes for the game before the Map because I need to reference them later.

```

class LaserWeaponArmory(Scene):

    def enter(self):
        print "You do a dive roll into the Weapon Armory, crouch and scan the room"
        print "for more Gothon's that might be hiding.  It's dead quiet, too quiet."
        print "You stand up and run to the far side of the room and find the"
        print "neutron bomb in its container.  There's a keypad lock on the box"
        print "and you need the code to get the bomb out.  If you get the code"
        print "wrong 10 times then the lock closes forever and you can't"
        print "get the bomb.  The code is 3 digits."
        code = "%d%d%d" % (randint(1,9), randint(1,9), randint(1,9))
        guess = raw_input("[keypad]> ")
        guesses = 0

        while guess != code and guesses < 10:
            print "BZZZZEDDD!"
            guesses += 1
            guess = raw_input("[keypad]> ")

        if guess == code:
            print "The container clicks open and the seal breaks, letting gas out."
            print "You grab the neutron bomb and run as fast as you can to the"
            print "bridge where you must place it in the right spot."
            return 'the_bridge'
        else:
            print "The lock buzzes one last time and then you hear a sickening"
            print "melting sound as the mechanism is fused together."
            print "You decide to sit there, and finally the Gothon's blow up the"
            print "ship from their ship and you die."
            return 'death'

class TheBridge(Scene):

```

```

def enter(self):
    print "You burst onto the Bridge with the netron destruct bomb"
    print "under your arm and surprise 5 Gothons who are trying to"
    print "take control of the ship. Each of them has an even uglier"
    print "clown costume than the last. They haven't pulled their"
    print "weapons out yet, as they see the active bomb under your"
    print "arm and don't want to set it off."

    action = raw_input("> ")

    if action == "throw the bomb":
        print "In a panic you throw the bomb at the group of Gothons"
        print "and make a leap for the door. Right as you drop it a"
        print "Gothon shoots you right in the back killing you."
        print "As you die you see another Gothon frantically try to disarm"
        print "the bomb. You die knowing they will probably blow up when"
        print "it goes off."
        return 'death'

    elif action == "slowly place the bomb":
        print "You point your blaster at the bomb under your arm"
        print "and the Gothons put their hands up and start to sweat."
        print "You inch backward to the door, open it, and then carefully"
        print "place the bomb on the floor, pointing your blaster at it."
        print "You then jump back through the door, punch the close button"
        print "and blast the lock so the Gothons can't get out."
        print "Now that the bomb is placed you run to the escape pod to"
        print "get off this tin can."
        return 'escape_pod'
    else:
        print "DOES NOT COMPUTE!"
        return "the_bridge"

class EscapePod(Scene):

    def enter(self):
        print "You rush through the ship desperately trying to make it to"
        print "the escape pod before the whole ship explodes. It seems like"
        print "hardly any Gothons are on the ship, so your run is clear of"
        print "interference. You get to the chamber with the escape pods, and"
        print "now need to pick one to take. Some of them could be damaged"
        print "but you don't have time to look. There's 5 pods, which one"
        print "do you take?"

        good_pod = randint(1,5)
        guess = raw_input("[pod #]> ")

        if int(guess) != good_pod:
            print "You jump into pod %s and hit the eject button." % guess
            print "The pod escapes out into the void of space, then"
            print "implodes as the hull ruptures, crushing your body"
            print "into jam jelly."
            return 'death'
        else:
            print "You jump into pod %s and hit the eject button." % guess
            print "The pod easily slides out into space heading to"
            print "the planet below. As it flies to the planet, you look"
            print "back and see your ship implode then explode like a"
            print "bright star, taking out the Gothon ship at the same"
            print "time. You won!"

            return 'finished'

```

This is the rest of the game's scenes, and since I know I need them and have thought about how they'll flow together I'm

able to code them up directly.

Incidentally, I wouldn't just type all this code in. Remember I said to try and build this incrementally, one little bit at a time. I'm just showing you the final result.

```
class Map(object):

    scenes = {
        'central_corridor': CentralCorridor(),
        'laser_weapon_armory': LaserWeaponArmory(),
        'the_bridge': TheBridge(),
        'escape_pod': EscapePod(),
        'death': Death()
    }

    def __init__(self, start_scene):
        self.start_scene = start_scene

    def next_scene(self, scene_name):
        return Map.scenes.get(scene_name)

    def opening_scene(self):
        return self.next_scene(self.start_scene)
```

After that I have my Map class, and you can see it is storing each scene by name in a dictionary, and then I refer to that dict with Map.scenes. This is also why the map comes after the scenes because the dictionary has to refer to them so they have to exist.

```
a_map = Map('central_corridor')
a_game = Engine(a_map)
a_game.play()
```

Finally I've got my code that runs the game by making a Map then handing that map to an Engine before calling play to make the game work.

## What You Should See

Make sure you understand the game and that you tried to solve it yourself first. One thing to do is if you're stumped, just go cheat a little bit. Take a look real quick in the book, then get your "Aha!" realization from my code, and go back to working on yours. Just try as hard as you can to solve it yourself first.

When I run my game it looks like this:

```
$ python ex43.py
```

```
-----
```

```
The Gothons of Planet Percal #25 have invaded your ship and destroyed
your entire crew. You are the last surviving member and your last
mission is to get the neutron destruct bomb from the Weapons Armory,
put it in the bridge, and blow the ship up after getting into an
```

*escape pod.*

*You're running down the central corridor to the Weapons Armory when a Gothon jumps out, red scaly skin, dark grimy teeth, and evil clown costume flowing around his hate filled body. He's blocking the door to the Armory and about to pull a weapon to blast you.*

*> dodge!*

*Like a world class boxer you dodge, weave, slip and slide right as the Gothon's blaster cranks a laser past your head.*

*In the middle of your artful dodge your foot slips and you bang your head on the metal wall and pass out.*

*You wake up shortly after only to die as the Gothon stomps on your head and eats you.*

*-----*

*I have a small puppy that's better at this.*

# Study Drills

1. I have a bug in this code. Why is the door lock guessing 11 times?
2. Explain how returning the next room works.
3. Add cheat codes to the game so you can get past the more difficult rooms. I can do this with two words on one line.
4. Go back to my description and analysis, then try to build a small combat system for the hero and the various Gothons he encounters.
5. This is actually a small version of something called a "finite state machine". Read about them. They might not make sense but try anyway.

# Common Student Questions

Where can I find stories for my own games?

You can make them up, just like you would tell a story to a friend. Or, you can also take simple scenes from a book or movie you like.

# Exercise 44: Inheritance Vs. Composition

In the fairy tales about heroes defeating evil villains there's always a dark forest of some kind. It could be a cave, a forest, another planet, just some place that everyone knows the hero shouldn't go. Of course, shortly after the villain is introduced you find out, yes, the hero has to go to that stupid forest to kill the bad guy. It seems the hero just keeps getting into situations that require him to risk his life in this evil forest.

You rarely read fairy tales about the heroes who are smart enough to just avoid the whole situation entirely. You never hear a hero say, "Wait a minute, if I leave to make my fortunes on the high seas leaving Buttercup behind I could die and then she'd have to marry some ugly prince named Humperdink. Humperdink! I think I'll stay here and start a Farm Boy For Rent business." If he did that there'd be no fire swamp, dying, reanimation, sword fights, giants, or any kind of story really. Because of this, the forest in these stories seems to exist like a black hole that drags the hero in no matter what they do.

In object oriented programming, Inheritance is the evil forest. Experienced programmers know to avoid this evil because they know that deep inside the Dark Forest Inheritance is the Evil Queen Multiple Inheritance. She likes to eat software and programmers with her massive complexity teeth, chewing on the flesh of the fallen. But, the forest is so powerful and so tempting that nearly every programmer has to go into it, and try to make it out alive with the Evil Queen's head before they can call themselves real programmers. You just can't resist the Inheritance Forest's pull, so you go in. After the adventure you learn to just stay out of that stupid forest and bring an army if you are ever forced to go in again.

This is basically a funny way to say that I'm going to teach you something you should avoid called Inheritance. Programmers who are currently in the forest battling the Queen will probably tell you that you have to go in. They say this because they need your help since what they've created is probably too much for them to handle. But, you should always remember this:

Most of the uses of inheritance can be simplified or replaced with composition, and multiple-inheritance should be avoided at all costs.

## What Is Inheritance?

Inheritance is used to indicate that one class will get most or all of its features from a parent class. This happens implicitly whenever you write `class Foo(Bar)` which says "Make a class *Foo* that inherits from *Bar*." When you do this, the language makes any action that you do on instances of *Foo* also work as if they were done to an instance of *Bar*. Doing this lets you put common functionality in the *Bar* class, then specialize that functionality in the *Foo* class as

needed.

When you are doing this kind of specialization, there's three ways that the parent and child classes can interact:

1. Actions on the child imply an action on the parent.
2. Actions on the child override the action on the parent.
3. Actions on the child alter the action on the parent.

I will now demonstrate each of these in order and show you code for them.

# Implicit Inheritance

First I will show you the implicit actions that happen when you define a function in the parent, but *not* in the child.

```
class Parent(object):
    def implicit(self):
        print "PARENT implicit()"

class Child(Parent):
    pass

dad = Parent()
son = Child()

dad.implicit()
son.implicit()
```

The use of *pass* under the `class Child:` is how you tell Python that you want an empty block. This creates a class named *Child* but says that there's nothing new to define in it. Instead it will inherit all of its behavior from *Parent*. When you run this code you get the following:

```
$ python ex44a.py
PARENT implicit()
PARENT implicit()
```

Notice how even though I'm calling `son.implicit()` on line 16, and even though *Child* does *not* have a *implicit* function defined, it still works and it calls the one defined in *Parent*. This shows you that, if you put functions in a base class (i.e. *Parent*) then all subclasses (i.e. *Child*) will automatically get those features. Very handy for repetitive code you need in many classes.

# Override Explicitly

The problem with implicitly having functions called is sometimes you want the child to behave differently. In this case you want to override the function in the child, effectively replacing the functionality. To do this just define a function with the same name in *Child*. Here's an example:

```
class Parent(object):
    def override(self):
```

```

    print "PARENT override()"

class Child(Parent):

    def override(self):
        print "CHILD override()"

dad = Parent()
son = Child()

dad.override()
son.override()

```

In this example I have a function named *override* in both classes, so let's see what happens when you run it.

```

$ python ex44b.py
PARENT override()
CHILD override()

```

As you can see, when line 14 runs, it runs the *Parent.override* function because that variable (*dad*) is a *Parent*. But, when line 15 runs it prints out the *Child.override* messages because *son* is an instance of *Child* and child overrides that function by defining it's own version.

Take a break right now and try playing with these two concepts before continuing.

## Alter Before Or After

The third way to use inheritance is a special case of overriding where you want to alter the behavior before or after you the parent class's version runs. You first override the function just like in the last example, but then you use a Python built-in function named *super* to get the *Parent* version to call. Here's the example of doing that so you can make sense of this description:

```

class Parent(object):

    def altered(self):
        print "PARENT altered()"

class Child(Parent):

    def altered(self):
        print "CHILD, BEFORE PARENT altered()"
        super(Child, self).altered()
        print "CHILD, AFTER PARENT altered()"

dad = Parent()
son = Child()

dad.altered()
son.altered()

```

The important lines here are 9-11, where in the child I do the following when *son.altered()* is called:

1. Because I've overridden *Parent.altered* the *Child.altered* version runs, and line 9 executes like you'd expect.
2. In this case I want to do a before and after so after line 9, I want to use *super* to get the *Parent.altered* version.

3. On line 10 I call `super(Child, self).altered()`, which is a lot like the *getattr* function you've used in the past, but it's aware of inheritance and will get the *Parent* class for you. You should be able to read this as "call *super* with arguments *Child* and *self*, then call the function *altered* on whatever it returns".
4. At this point, the *Parent.altered* version of the function runs, and that prints out the parent message.
5. Finally, this returns from the *Parent.altered* and the *Child.altered* function continues to print out the after message.

If you then run this you should see this:

```
$ python ex44c.py
PARENT altered()
CHILD, BEFORE PARENT altered()
PARENT altered()
CHILD, AFTER PARENT altered()
```

## All Three Combined

To demonstrate all of these, I have a final version that shows each kind of interaction from inheritance in one file:

```
class Parent(object):
    def override(self):
        print "PARENT override()"

    def implicit(self):
        print "PARENT implicit()"

    def altered(self):
        print "PARENT altered()"

class Child(Parent):
    def override(self):
        print "CHILD override()"

    def altered(self):
        print "CHILD, BEFORE PARENT altered()"
        super(Child, self).altered()
        print "CHILD, AFTER PARENT altered()"

dad = Parent()
son = Child()

dad.implicit()
son.implicit()

dad.override()
son.override()

dad.altered()
son.altered()
```

Go through each line of this code, and write a comment explaining what that line does and whether it's an override or not. Then, run it and see that you get what you expected:

```
$ python ex44d.py
PARENT implicit()
PARENT implicit()
```

```
PARENT override()  
CHILD override()  
PARENT altered()  
CHILD, BEFORE PARENT altered()  
PARENT altered()  
CHILD, AFTER PARENT altered()
```

# The Reason For `super()`

This should seem like commons sense, but then we get into trouble with a thing called Multiple Inheritance. Multiple Inheritance is when you define a class that inherits from one or *more* classes, like this:

```
class SuperFun(Child, BadStuff):  
    pass
```

This is like saying, "Make a class named *SuperFun* that inherits from the classes *Child* and *BadStuff* at the same time."

In this case, whenever you have implicit actions on any *SuperFun* instance, Python has to lookup the possible function in the class hierarchy for both *Child* and *BadStuff*, but it needs to do this in a consistent order. To do this Python uses something called "Method Resolution Order" (MRO) and an algorithm called C3 to get it straight.

Because the MRO is complex, and a well defined algorithm is used, Python can't leave it to you to get it right. That'd be annoying wouldn't it? Instead, Python gives you the *super()* function which handles all of this for you in the places that you need the altering type of actions as I did in *Child.altered* above. With *super()* you don't have to worry about getting this right, and Python will find the right function for you.

## Using `super()` With `__init__`

The most common use of *super()* is actually in `__init__` functions in base classes. This is usually the only place where you need to do some things in a child, then complete the initialization in the parent. Here's a quick example of doing that in the *Child* from these examples:

```
class Child(Parent):  
  
    def __init__(self, stuff):  
        self.stuff = stuff  
        super(Child, self).__init__()
```

This is pretty much the same as the *Child.altered* example above, except I'm setting some variables in the `__init__` before having the *Parent* initialize with its *Parent.\_\_init\_\_*.

# Composition

Inheritance is useful, but another way to do the exact same thing is just to *use* other classes and modules, rather than rely on implicit inheritance. If you look at the three ways to exploit inheritance, two of the three involve writing new code to replace or alter functionality. This can easily be replicated by just calling functions in a module. Here's an example of

doing this:

```
class Other(object):

    def override(self):
        print "OTHER override()"

    def implicit(self):
        print "OTHER implicit()"

    def altered(self):
        print "OTHER altered()"

class Child(object):

    def __init__(self):
        self.other = Other()

    def implicit(self):
        self.other.implicit()

    def override(self):
        print "CHILD override()"

    def altered(self):
        print "CHILD, BEFORE OTHER altered()"
        self.other.altered()
        print "CHILD, AFTER OTHER altered()"

son = Child()

son.implicit()
son.override()
son.altered()
```

In this code I'm not using the name *Parent*, since there is *not* a parent-child is-a relationship. This is a has-a relationship, where *Child* has-a *Other* that it uses to get its work done. When I run this I get the following output:

```
$ python ex44e.py
OTHER implicit()
CHILD override()
CHILD, BEFORE OTHER altered()
OTHER altered()
CHILD, AFTER OTHER altered()
```

You can see that most of the code in *Child* and *Other* is the same to accomplish the same thing. The only difference is that I had to define a *Child.implicit* function to do that one action. I could then ask myself if I need this *Other* to be a class, and could I just make it into a module named *other.py*?

# When To Use Inheritance Or Composition

The question of "inheritance vs. composition" comes down to an attempt to solve the problem of reusable code. You don't want to have duplicated code all over your code, since that's not clean and efficient. Inheritance solves this problem by creating a mechanism for you to have implied features in base classes. Composition solves this by giving you

modules and the ability to simply call functions in other classes.

If both solutions solve the problem of reuse, then which one is appropriate in which situations? The answer is incredibly subjective, but I'll give you my three guidelines for when to do which:

1. Avoid multiple inheritance at all costs, as it's too complex to be useful reliably. If you're stuck with it, then be prepared to know the class hierarchy and spend time finding where everything is coming from.
2. Use composition to package up code into modules that is used in many different unrelated places and situations.
3. Use inheritance only when there are clearly related reusable pieces of code that fit under a single common concept, or if you have to because of something you're using.

However, do not be a slave to these rules. The thing to remember about object oriented programming is that it is entirely a social convention programmers have created to package and share code. Because it's a social convention, but one that's codified in Python, you may be forced to avoid these rules because of the people you work with. In that case, find out how they use things and then just adapt to the situation.

## Study Drills

There is only one extra credit for this exercise because it is a big exercise. Go and read this <http://www.python.org/dev/peps/pep-0008/> and start trying to use it in your code. You'll notice that some of it is different from what you've been learning in this book, but now you should be able to understand their recommendations and use them in your own code. The rest of the code in this book may or may not follow these guidelines depending on if it makes the code more confusing. I suggest you also do this, as comprehension is more important than impressing everyone with you knowledge of esoteric style rules.

## Common Student Questions

How do I get better at solving problems that I haven't seen before?

The only way to get better at solving problems is to solve as many problems as you can *by yourself*. Typically people hit a difficult problem and then rush out to find an answer. This is fine when you have to get things done, but if you have the time to solve it yourself, then take that time. Stop and bang your head against the problem for as long as possible, trying every possible thing, until you solve it or give up. After that the answers you find will be more satisfying and you'll eventually get better at solving problems.

Aren't objects just copies of classes?

In some languages (like JavaScript) that is true. These are called prototype languages and there's not many differences between objects and classes other than usage. In Python however classes act as templates that "mint" new objects, similar to how coins were minted using a die (template).

# Exercise 45: You Make A Game

You need to start learning to feed yourself. Hopefully as you have worked through this book, you have learned that all the information you need is on the internet, you just have to go search for it. The only thing you have been missing are the right words and what to look for when you search. Now you should have a sense of it, so it's about time you struggled through a big project and tried to get it working.

Here are your requirements:

1. Make a different game from the one I made.
2. Use more than one file, and use `import` to use them. Make sure you know what that is.
3. Use *one class per room* and give the classes names that fit their purpose. Like `GoldRoom`, `KoiPondRoom`.
4. Your runner will need to know about these rooms, so make a class that runs them and knows about them. There's plenty of ways to do this, but consider having each room return what room is next or setting a variable of what room is next.

Other than that I leave it to you. Spend a whole week on this and make it the best game you can. Use classes, functions, dicts, lists anything you can to make it nice. The purpose of this lesson is to teach you how to structure classes that need other classes inside other files.

Remember, I'm not telling you *exactly* how to do this because you have to do this yourself. Go figure it out. Programming is problem solving, and that means trying things, experimenting, failing, scrapping your work, and trying again. When you get stuck, ask for help and show people your code. If they are mean to you, ignore them, focus on the people who are not mean and offer to help. Keep working it and cleaning it until it's good, then show it some more.

Good luck, and see you in a week with your game.

## Evaluating Your Game

In this exercise you will evaluate the game you just made. Maybe you got part-way through it and you got stuck. Maybe you got it working but just barely. Either way, we're going to go through a bunch of things you should know now and make sure you covered them in your game. We're going to study how to properly format a class, common conventions in using classes, and a lot of "textbook" knowledge.

Why would I have you try to do it yourself and then show you how to do it right? From now on in the book I'm going to try to make you self-sufficient. I've been holding your hand mostly this whole time, and I can't do that for much longer. I'm now instead going to give you things to do, have you do them on your own, and then give you ways to improve what

you did.

You will struggle at first and probably be very frustrated but stick with it and eventually you will build a mind for solving problems. You will start to find creative solutions to problems rather than just copy solutions out of textbooks.

# Function Style

All the other rules I've taught you about how to make a function nice apply here, but add these things:

- For various reasons, programmers call functions that are part of classes `methods`. It's mostly marketing but just be warned that every time you say "function" they'll annoyingly correct you and say "method". If they get too annoying, just ask them to demonstrate the mathematical basis that determines how a "method" is different from a "function" and they'll shut up.
- When you work with classes much of your time is spent talking about making the class "do things". Instead of naming your functions after what the function does, instead name it as if it's a command you are giving to the class. Same as `pop` is saying "Hey list, `pop` this off." It isn't called `remove_from_end_of_list` because even though that's what it does, that's not a *command* to a list.
- Keep your functions small and simple. For some reason when people start learning about classes they forget this.

# Class Style

- Your class should use "camel case" like `SuperGoldFactory` rather than `super_gold_factory`.
- Try not to do too much in your `__init__` functions. It makes them harder to use.
- Your other functions should use "underscore format" so write `my_awesome_hair` and not `myawesomehair` or `MyAwesomeHair`.
- Be consistent in how you organize your function arguments. If your class has to deal with users, dogs, and cats, keep that order throughout unless it really doesn't make sense. If you have one function takes `(dog, cat, user)` and the other takes `(user, cat, dog)`, it'll be hard to use.
- Try not to use variables that come from the module or globals. They should be fairly self-contained.
- A foolish consistency is the hobgoblin of little minds. Consistency is good, but foolishly following some idiotic mantra because everyone else does is bad style. Think for yourself.
- Always, *always* have `class Name(object)` format or else you will be in big trouble.

# Code Style

- Give your code vertical space so people can read it. You will find some very bad programmers who are able to write reasonable code, but who do not add *any* spaces. This is bad style in any language because the human eye and brain use space and vertical alignment to scan and separate visual elements. Not having space is the same as giving your code an awesome camouflage paint job.
- If you can't read it out loud, it's probably hard to read. If you are having a problem making something easy to use, try reading it out loud. Not only does this force you to slow down and really read it, but it also helps you find difficult passages and things to change for readability.
- Try to do what other people are doing in Python until you find your own style.

- Once you find your own style, do not be a jerk about it. Working with other people's code is part of being a programmer, and other people have really bad taste. Trust me, you will probably have really bad taste too and not even realize it.
- If you find someone who writes code in a style you like, try writing something that mimics their style.

# Good Comments

- There are programmers who will tell you that your code should be readable enough that you do not need comments. They'll then tell you in their most official sounding voice that, "Ergo you should never write comments." Those programmers are either consultants who get paid more if other people can't use their code, or incompetents who tend to never work with other people. Ignore them and write comments.
- When you write comments, describe *why* you are doing what you are doing. The code already says how, but why you did things the way you did is more important.
- When you write doc comments for your functions , make the comments documentation for someone who will have to use your code. You do not have to go crazy, but a nice little sentence about what someone does with that function helps a lot.
- Finally, while comments are good, too many are bad, and you have to maintain them. Keep your comments relatively short and to the point, and if you change a function, review the comment to make sure it's still correct.

# Evaluate Your Game

I want you now to pretend you are me. Adopt a very stern look, print out your code, and take a red pen and mark every mistake you find. Anything from this exercise and from other things you have known. Once you are done marking your code up, I want you to fix everything you came up with. Then repeat this a couple of times, looking for anything that could be better. Use all the tricks I've given you to break your code down into the smallest tiniest little analysis you can.

The purpose of this exercise is to train your attention to detail on classes. Once you are done with this bit of code, find someone else's code and do the same thing. Go through a printed copy of some part of it and point out all the mistakes and style errors you find. Then fix it and see if your fixes can be done without breaking their program.

I want you to do nothing but evaluate and fix code for the week. Your own code and other people's. It'll be pretty hard work, but when you are done your brain will be wired tight like a boxer's hands.

# Exercise 46: A Project Skeleton

This will be where you start learning how to setup a good project "skeleton" directory. This skeleton directory will have all the basics you need to get a new project up and running. It will have your project layout, automated tests, modules, and install scripts. When you go to make a new project, just copy this directory to a new name and edit the files to get started.

## Skeleton Contents

First, create the structure of your skeleton directory with these commands:

```
$ mkdir projects
$ cd projects/
$ mkdir skeleton
$ cd skeleton
$ mkdir bin
$ mkdir NAME
$ mkdir tests
$ mkdir docs
```

I use a directory named `projects` to store all the various things I'm working on. Inside that directory I have my `skeleton` directory that I put the basis of my projects into. The directory `NAME` will be renamed to whatever you are calling your project's main module when you use the skeleton.

Next we need to setup some initial files. Here's how you do that on Linux/OSX:

```
$ touch NAME/__init__.py
$ touch tests/__init__.py
```

Here's the same thing on Windows PowerShell:

```
$ new-item -type file NAME/__init__.py
$ new-item -type file tests/__init__.py
```

That creates empty Python module directories we can put our code in. Then we need to create a `setup.py` file we can use to install our project later if we want:

```
try:
    from setuptools import setup
except ImportError:
    from distutils.core import setup

config = {
    'description': 'My Project',
    'author': 'My Name',
    'url': 'URL to get it at.',
    'download_url': 'Where to download it.',
    'author_email': 'My email.',
    'version': '0.1',
    'install_requires': ['nose'],
    'packages': ['NAME'],
    'scripts': [],
    'name': 'projectname'
}

setup(**config)
```

Edit this file so that it has your contact information and is ready to go for when you copy it.

Finally you will want a simple skeleton file for tests named `tests/NAME_tests.py`:

```
from nose.tools import *
import NAME

def setup():
    print "SETUP!"

def teardown():
    print "TEAR DOWN!"

def test_basic():
    print "I RAN!"
```

# Final Directory Structure

When you are done setting all of this up, your directory should look like mine here:

```
$ ls -R
NAME                bin                docs                setup.py            tests

./NAME:
__init__.py

./bin:

./docs:

./tests:
NAME_tests.py      __init__.py
```

This is on unix, but the structure is the same on Windows, and if I were to draw it out as a tree:

```
setup.py
NAME/
    __init__.py
```

```
bin/
docs/
tests/
    NAME_tests.py
    __init__.py
```

And from now on, you should run your commands from that work with this directory from this point. If you can't to `ls -R` and see this same structure, then you are in the wrong place. For example, people commonly go into the `tests/` directory to try to run files there, which won't work. To run your application's tests, you would need to be *above* `tests/` and this location I have above. So, if you try this:

```
$ cd tests/    # WRONG! WRONG! WRONG!
$ nosetests
```

```
-----
Ran 0 tests in 0.000s
```

```
OK
```

Then that is *wrong*! You have to be above tests, so assuming you made this mistake, you would fix it by doing:

```
$ cd ..    # get out of tests/
$ ls      # CORRECT! you are now in the right spot
NAME      bin      docs      setup.py      tests
$ nosetests
```

```
-----
Ran 1 test in 0.004s
```

```
OK
```

Remember this because people make this mistake quite frequently.

# Installing Python Packages

Make sure you have some packages installed that makes these things work. Here's the problem though. You are at a point where it's difficult for me to help you do that and keep this book sane and clean. There are so many ways to install software on so many computers that I'd have to spend 10 pages walking you through every step, and let me tell you I am a lazy guy.

Rather than tell you how to do it exactly, I'm going to tell you what you should install, and then tell you to figure it out and get it working. This will be really good for you since it will open a whole world of software you can use that other people have released to the world.

Next, install the following python packages:

1. pip from <http://pypi.python.org/pypi/pip>
2. distribute from <http://pypi.python.org/pypi/distribute>
3. nose from <http://pypi.python.org/pypi/nose/>
4. virtualenv from <http://pypi.python.org/pypi/virtualenv>

Do not just download these packages and install them by hand. Instead see how other people recommend you install these packages and use them for your particular system. The process will be different for most versions of Linux, OSX, and definitely different for Windows.

I am warning you, this will be frustrating. In the business we call this "yak shaving". Yak shaving is any activity that is mind numbingly irritatingly boring and tedious that you have to do before you can do something else that's more fun. You want to create cool Python projects, but you can't do that until you setup a skeleton directory, but you can't setup a skeleton directory until you install some packages, but you can't install packages until you install package installers, and you can't install package installers until you figure out how your system installs software in general, and so on.

Struggle through this anyway. Consider it your trial-by-annoyance to get into the programmer club. Every programmer has to do these annoying tedious tasks before they can do something cool.

# Testing Your Setup

After you get all that installed you should be able to do this:

```
$ nosetests
.
-----
Ran 1 test in 0.007s

OK
```

I'll explain what this `nosetests` thing is doing in the next exercise, but for now if you do not see that, you probably got something wrong. Make sure you put `__init__.py` files in your `NAME` and `tests` directory and make sure you got `tests/NAME_tests.py` right.

# Using The Skeleton

You are now done with most of your yak shaving. Whenever you want to start a new project, just do this:

1. Make a copy of your skeleton directory. Name it after your new project.
2. Rename (move) the `NAME` module to be the name of your project or whatever you want to call your root module.
3. Edit your `setup.py` to have all the information for your project.
4. Rename `tests/NAME_tests.py` to also have your module name.
5. Double check it's all working using `nosetests` again.
6. Start coding.

# Required Quiz

This exercise doesn't have extra credit but a quiz you should complete:

1. Read about how to use all of the things you installed.
2. Read about the `setup.py` file and all it has to offer. Warning, it is not a very well-written piece of software, so it

will be very strange to use.

3. Make a project and start putting code into the module, then get the module working.
4. Put a script in the `bin` directory that you can run. Read about how you can make a Python script that's runnable for your system.
5. Mention the `bin` script you created in your `setup.py` so that it gets installed.
6. Use your `setup.py` to install your own module and make sure it works, then use `pip` to uninstall it.

# Common Student Questions

Do these instructions work on Windows?

They should, but depending on the version of Windows you may need to struggle with the setup a bit to get it working. Just keep researching and trying it until you get it, or see if you can ask a more experienced Python+Windows friend to help out.

It seems I can't run `nosetests` on Windows?

Sometimes the Python installer does not add the `C:\Python27\Script` to the system `PATH`. If this is the case for you, go back and add this to the path just like you did for `C:\Python27` in Exercise 0.

What do I put in the config dictionary in my `setup.py`

Make sure you read the documentation for `distutils` at <http://docs.python.org/distutils/setupscript.html>

I can't seem to load the `NAME` module and just get an `ImportError`.

Make sure you made the `NAME/__init__.py` file. If you're on Windows make sure you didn't accidentally name it `NAME/__init__.py.txt` which happens by default with some editors.

Why do we need a `bin/` folder at all?

This is just a standard place to put scripts that are run on the command line, not a place to put modules.

Do you have a real world example project?

There are many projects written in Python that do this, but try this simple one I created <https://gitorious.org/python-modargs>

My `nosetests` run only shows one test being run. Is that right?

Yes, that's what my output shows too.

# Exercise 47: Automated Testing

Having to type commands into your game over and over to make sure it's working is annoying. Wouldn't it be better to write little pieces of code that test your code? Then when you make a change, or add a new thing to your program, you just "run your tests" and the tests make sure things are still working. These automated tests won't catch all your bugs, but they will cut down on the time you spend repeatedly typing and running your code.

Every exercise after this one will not have a `What You Should See` section, but instead it will have a `What You Should Test` section. You will be writing automated tests for all of your code starting now, and this will hopefully make you an even better programmer.

I won't try to explain why you should write automated tests. I will only say that, you are trying to be a programmer, and programmers automate boring and tedious tasks. Testing a piece of software is definitely boring and tedious, so you might as well write a little bit of code to do it for you.

That should be all the explanation you need because *your* reason for writing unit tests is to make your brain stronger. You have gone through this book writing code to do things. Now you are going to take the next leap and write code that knows about other code you have written. This process of writing a test that runs some code you have written *forces* you to understand clearly what you have just written. It solidifies in your brain exactly what it does and why it works and gives you a new level of attention to detail.

## Writing A Test Case

We're going to take a very simple piece of code and write one simple test. We're going to base this little test on a new project from your project skeleton.

First, make a `ex47` project from your project skeleton. Make sure you do it right and rename the module and get that first `tests/ex47_tests.py` test file going right. Also make sure nose runs this test file. *IMPORTANT* make sure you also delete `tests/skel_tests.pyc` if it's there.

### Note

Remember that you run the command `nosetests` to run the tests. You can run them with `python ex46_tests.py` but it won't work as easily and you'll have to do it for each test file.

Next, create a simple file `ex47/game.py` where you can put the code to test. This will be a very silly little class that we want to test with this code in it:

```
class Room(object):

    def __init__(self, name, description):
        self.name = name
        self.description = description
        self.paths = {}

    def go(self, direction):
        return self.paths.get(direction, None)

    def add_paths(self, paths):
        self.paths.update(paths)
```

Once you have that file, change unit test skeleton to this:

```
from nose.tools import *
from ex47.game import Room

def test_room():
    gold = Room("GoldRoom",
        """This room has gold in it you can grab. There's a
        door to the north.""")
    assert_equal(gold.name, "GoldRoom")
    assert_equal(gold.paths, {})

def test_room_paths():
    center = Room("Center", "Test room in the center.")
    north = Room("North", "Test room in the north.")
    south = Room("South", "Test room in the south.")

    center.add_paths({'north': north, 'south': south})
    assert_equal(center.go('north'), north)
    assert_equal(center.go('south'), south)

def test_map():
    start = Room("Start", "You can go west and down a hole.")
    west = Room("Trees", "There are trees here, you can go east.")
    down = Room("Dungeon", "It's dark down here, you can go up.")

    start.add_paths({'west': west, 'down': down})
    west.add_paths({'east': start})
    down.add_paths({'up': start})

    assert_equal(start.go('west'), west)
    assert_equal(start.go('west').go('east'), start)
    assert_equal(start.go('down').go('up'), start)
```

This file imports the `Room` class you made in the `ex47.game` module so that you can do tests on it. There are then a set of tests that are functions starting with `test_`. Inside each test case there's a bit of code that makes a `Room` or a set of `Rooms`, and then makes sure the rooms work the way you expect them to work. It tests out the basic room features, then the paths, then tries out a whole map.

The important functions here are `assert_equal` which makes sure that variables you have set or paths you have built in a `Room` are actually what you think they are. If you get the wrong result, then `nosetests` will print out an error message so you can go figure it out.

# Testing Guidelines

Follow these general loose set of guidelines when making your tests:

1. Test files go in `tests/` and are named `BLAH_tests.py` otherwise `nosetests` won't run them. This also keeps your tests from clashing with your other code.
2. Write one test file for each module you make.
3. Keep your test cases (functions) short, but do not worry if they are a bit messy. Test cases are usually kind of messy.
4. Even though test cases are messy, try to keep them clean and remove any repetitive code you can. Create helper functions that get rid of duplicate code. You will thank me later when you make a change and then have to change your tests. Duplicated code will make changing your tests more difficult.
5. Finally, do not get too attached to your tests. Sometimes, the best way to redesign something is to just delete it, the tests, and start over.

## What You Should See

```
$ python ex47.py
```

That's what you should see if everything is working right. Try causing an error to see what that looks like and then fix it.

## Study Drills

1. Go read about `nosetests` more, and also read about alternatives.
2. Learn about Python's "doc tests" and see if you like them better.
3. Make your Room more advanced, and then use it to rebuild your game yet again but this time, unit test as you go.

## Common Student Questions

I get a syntax error when I run `nosetests`.

If you get that then look at what the error says and fix that line of code or the ones above it. Tools like `nosetests` are running your code and the test code, so they will find syntax errors the same as running `python` will.

I can't import `ex47.game`?

Make sure you create the `ex47/__init__.py` file. Refer to Exercise 47 again to see how it's done. If that's not the problem then do this on OSX/Linux:

```
export PYTHONPATH=.
```

And on Windows do:

```
$env:PYTHONPATH = "$env:PYTHONPATH;."
```

Finally, make sure you're running ther tests with `nosetests` not with just `python`.

I get **UserWarning** when I run `nosetests`.

You probably have two versions of Python installed or you aren't using `distribute`. Go back and install `distribute` or `pip` as I describe in Exercise 46.

# Exercise 48: Advanced User Input

Your game probably was coming along great, but I bet how you handled what the user typed was becoming tedious. Each room needed its own very exact set of phrases that only worked if your player typed them perfectly. What you'd rather have is a device that lets users type phrases in various ways. For example, we'd like to have all of these phrases work the same:

- open door
- open the door
- go THROUGH the door
- punch bear
- Punch The Bear in the FACE

It should be alright for a user to write something a lot like English for your game, and have your game figure out what it means. To do this, we're going to write a module that does just that. This module will have a few classes that work together to handle user input and convert it into something your game can work with reliably.

In a simple version of English the following elements:

- Words separated by spaces.
- Sentences composed of the words.
- Grammar that structures the sentences into meaning.

That means the best place to start is figuring out how to get words from the user and what kinds of words those are.

## Our Game Lexicon

In our game we have to create a Lexicon of words:

- Direction words: north, south, east, west, down, up, left, right, back.
- Verbs: go, stop, kill, eat.
- Stop words: the, in, of, from, at, it
- Nouns: door, bear, princess, cabinet.
- Numbers: any string of 0 through 9 characters.

When we get to nouns, we have a slight problem since each room could have a different set of Nouns, but let's just pick

this small set to work with for now and improve it later.

# Breaking Up A Sentence

Once we have our lexicon of words we need a way to break up sentences so that we can figure out what they are. In our case, we've defined a sentence as "words separated by spaces", so we really just need to do this:

```
stuff = raw_input('> ')
words = stuff.split()
```

That's really all we'll worry about for now, but this will work really well for quite a while.

# Lexicon Tuples

Once we know how to break up a sentence into words, we just have to go through the list of words and figure out what "type" they are. To do that we're going to use a handy little Python structure called a "tuple". A tuple is nothing more than a list that you can't modify. It's created by putting data inside two ( ) with a comma, like a list:

```
first_word = ('direction', 'north')
second_word = ('verb', 'go')
sentence = [first_word, second_word]
```

This creates a pair of (TYPE, WORD) that lets you look at the word and do things with it.

This is just an example, but that's basically the end result. You want to take raw input from the user, carve it into words with `split`, then analyze those words to identify their type, and finally make a sentence out of them.

# Scanning Input

Now you are ready to write your scanner. This scanner will take a string of raw input from a user and return a sentence that's composed of a list of tuples with the (TOKEN, WORD) pairings. If a word isn't part of the lexicon then it should still return the WORD, but set the TOKEN to an error token. These error tokens will tell the user they messed up.

Here's where it gets fun. I'm not going to tell you how to do this. Instead I'm going to write a `unit test` and you are going to write the scanner so that the unit test works.

# Exceptions And Numbers

There is one tiny thing I will help you with first, and that's converting numbers. In order to do this though, we're going to cheat and use exceptions. An exception is an error that you get from some function you may have run. What happens is your function "raises" an exception when it encounters an error, then you have to handle that exception. For example, if you type this into python:

```
~/projects/simplegame $ python
```

```
Python 2.6.5 (r265:79063, Apr 16 2010, 13:57:41)
[GCC 4.4.3] on linux2
Type "help", "copyright", "credits" or "license" for more information.
>>> int("hell")
Traceback (most recent call last):
  File "<stdin>", line 1, in <module>
ValueError: invalid literal for int() with base 10: 'hell'
>>
```

That `ValueError` is an exception that the `int()` function threw because what you handed `int()` is not a number. The `int()` function could have returned a value to tell you it had an error, but since it only returns integers, it'd have a hard time doing that. It can't return -1 since that's a number. Instead of trying to figure out what to return when there's an error, the `int()` function raises the `ValueError` exception and you deal with it.

You deal with an exception by using the `try` and `except` keywords:

```
def convert_number(s):
    try:
        return int(s)
    except ValueError:
        return None
```

You put the code you want to "try" inside the `try` block, and then you put the code to run for the error inside the `except`. In this case, we want to "try" to call `int()` on something that might be a number. If that has an error, then we "catch" it and return `None`.

In your scanner that you write, you should use this function to test if something is a number. You should also do it as the last thing you check for before declaring that word an error word.

# What You Should Test

Here are the files `tests/lexicon_tests.py` that you should use:

```
from nose.tools import *
from ex48 import lexicon

def test_directions():
    assert_equal(lexicon.scan("north"), [('direction', 'north')])
    result = lexicon.scan("north south east")
    assert_equal(result, [('direction', 'north'),
                          ('direction', 'south'),
                          ('direction', 'east')])

def test_verbs():
    assert_equal(lexicon.scan("go"), [('verb', 'go')])
    result = lexicon.scan("go kill eat")
    assert_equal(result, [('verb', 'go'),
                          ('verb', 'kill'),
                          ('verb', 'eat')])

def test_stops():
    assert_equal(lexicon.scan("the"), [('stop', 'the')])
    result = lexicon.scan("the in of")
```

```

assert_equal(result, [('stop', 'the'),
                      ('stop', 'in'),
                      ('stop', 'of')])

def test_nouns():
    assert_equal(lexicon.scan("bear"), [('noun', 'bear')])
    result = lexicon.scan("bear princess")
    assert_equal(result, [('noun', 'bear'),
                          ('noun', 'princess')])

def test_numbers():
    assert_equal(lexicon.scan("1234"), [('number', 1234)])
    result = lexicon.scan("3 91234")
    assert_equal(result, [('number', 3),
                          ('number', 91234)])

def test_errors():
    assert_equal(lexicon.scan("ASDFADFASDF"), [('error', 'ASDFADFASDF')])
    result = lexicon.scan("bear IAS princess")
    assert_equal(result, [('noun', 'bear'),
                          ('error', 'IAS'),
                          ('noun', 'princess')])

```

Remember that you will want to make a new project with your skeleton, type in this test case (do not copy-paste!) and write your scanner so that the test runs. Focus on the details and make sure everything works right.

## Design Hints

Focus on getting one test working at a time. Keep this simple and just put all the words in your lexicon in lists that are in your `lexicon.py` module. Do not modify the input list of words, but instead make your own new list with your lexicon tuples in it. Also, use the `in` keyword with these lexicon lists to check if a word is in the lexicon.

## Study Drills

1. Improve the unit test to make sure you cover more of the lexicon.
2. Add to the lexicon and then update the unit test.
3. Make your scanner handles user input in any capitalization and case. Update the test to make sure this actually works.
4. Find another way to convert the number.
5. My solution was 37 lines long. Is yours longer? Shorter?

## Common Student Questions

Why do I keep getting `ImportErrors`?

Import errors are caused by usually four things. 1) You didn't make a `__init__.py` in a directory that has modules in it. 2) you are in the wrong directory. 3) You are importing the wrong module because you spelled it wrong. 4) Your `PYTHONPATH` isn't set to `.` so you can't load modules from your current directory.

What's the difference between `try-except` and `if-else`?

The `try-except` construct is only used for handling exceptions that modules can throw. It should *never* be used as an alternative to `if-else`.

Is there a way to keep the game running while the user is waiting to type?

I'm assuming you want to have a monster attack the user if they don't react quick enough. It is possible but it involves modules and techniques that are outside of this book's domain.

# Exercise 49: Making Sentences

What we should be able to get from our little game lexicon scanner is a list that looks like this:

```
>>> from ex48 import lexicon
>>> print lexicon.scan("go north")
[('verb', 'go'), ('direction', 'north')]
>>> print lexicon.scan("kill the princess")
[('verb', 'kill'), ('stop', 'the'), ('noun', 'princess')]
>>> print lexicon.scan("eat the bear")
[('verb', 'eat'), ('stop', 'the'), ('noun', 'bear')]
>>> print lexicon.scan("open the door and smack the bear in the nose")
[('error', 'open'), ('stop', 'the'), ('noun', 'door'), ('error', 'and'),
 ('error', 'smack'), ('stop', 'the'), ('noun', 'bear'), ('stop', 'in'),
 ('stop', 'the'), ('error', 'nose')]
>>>
```

Now let us turn this into something the game can work with, which would be some kind of Sentence class.

If you remember grade school, a sentence can be a simple structure like:

Subject Verb Object

Obviously it gets more complex than that, and you probably did many days of annoying sentence graphs for English class. What we want is to turn the above lists of tuples into a nice Sentence object that has subject, verb, and object.

## Match And Peek

To do this we need four tools:

1. A way to loop through the list of tuples. That's easy.
2. A way to "match" different types of tuples that we expect in our Subject Verb Object setup.
3. A way to "peek" at a potential tuple so we can make some decisions.
4. A way to "skip" things we do not care about, like stop words.

We will be putting these functions in a file named `ex48/parser.py` in order to test it. We use the peek function to say look at the next element in our tuple list, and then match to take one off and work with it. Let's take a look at a first peek function:

```
def peek(word_list):
    if word_list:
```

```

    word = word_list[0]
    return word[0]
else:
    return None

```

Very easy. Now for the match function:

```

def match(word_list, expecting):
    if word_list:
        word = word_list.pop(0)

        if word[0] == expecting:
            return word
        else:
            return None
    else:
        return None

```

Again, very easy, and finally our skip function:

```

def skip(word_list, word_type):
    while peek(word_list) == word_type:
        match(word_list, word_type)

```

By now you should be able to figure out what these do. Make sure you understand them.

# The Sentence Grammar

With our tools we can now begin to build Sentence objects from our list of tuples. What we do is a process of:

1. Identify the next word with `peek`.
2. If that word fits in our grammar, we call a function to handle that part of the grammar, say `parse_subject`.
3. If it doesn't, we `raise` an error, which you will learn about in this lesson.
4. When we're all done, we should have a Sentence object to work with in our game.

The best way to demonstrate this is to give you the code to read, but here's where this exercise is different from the previous one: You will write the test for the parser code I give you. Rather than giving you the test so you can write the code, I will give you the code, and you have to write the test.

Here's the code that I wrote for parsing simple sentences using the `ex48.lexicon` module:

```

class ParserError(Exception):
    pass

class Sentence(object):

    def __init__(self, subject, verb, object):
        # remember we take ('noun','princess') tuples and convert them
        self.subject = subject[1]
        self.verb = verb[1]
        self.object = object[1]

```

```

def peek(word_list):
    if word_list:
        word = word_list[0]
        return word[0]
    else:
        return None

def match(word_list, expecting):
    if word_list:
        word = word_list.pop(0)

        if word[0] == expecting:
            return word
        else:
            return None
    else:
        return None

def skip(word_list, word_type):
    while peek(word_list) == word_type:
        match(word_list, word_type)

def parse_verb(word_list):
    skip(word_list, 'stop')

    if peek(word_list) == 'verb':
        return match(word_list, 'verb')
    else:
        raise ParserError("Expected a verb next.")

def parse_object(word_list):
    skip(word_list, 'stop')
    next = peek(word_list)

    if next == 'noun':
        return match(word_list, 'noun')
    if next == 'direction':
        return match(word_list, 'direction')
    else:
        raise ParserError("Expected a noun or direction next.")

def parse_subject(word_list, subj):
    verb = parse_verb(word_list)
    obj = parse_object(word_list)

    return Sentence(subj, verb, obj)

def parse_sentence(word_list):
    skip(word_list, 'stop')

    start = peek(word_list)

    if start == 'noun':
        subj = match(word_list, 'noun')
        return parse_subject(word_list, subj)
    elif start == 'verb':
        # assume the subject is the player then
        return parse_subject(word_list, ('noun', 'player'))
    else:
        raise ParserError("Must start with subject, object, or verb not: %s" % start)

```

# A Word On Exceptions

You briefly learned about exceptions, but not how to raise them. This code demonstrates how to do that with the `ParserError` at the top. Notice that it uses classes to give it the type of `Exception`. Also notice the use of `raise` keyword to raise the exception.

In your tests, you will want to work with these exceptions, which I'll show you how to do.

## What You Should Test

For Exercise 49 is write a complete test that confirms everything in this code is working. Put the test in `tests/parser_tests.py` similar to the test file from the last exercise. That includes making exceptions happen by giving it bad sentences.

Check for an exception by using the function `assert_raises` from the nose documentation. Learn how to use this so you can write a test that is *expected* to fail, which is very important in testing. Learn about this function (and others) by reading the nose documentation.

When you are done, you should know how this bit of code works, and how to write a test for other people's code even if they do not want you to. Trust me, it's a very handy skill to have.

## Study Drills

1. Change the `parse_` methods and try to put them into a class rather than be just methods. Which design do you like better?
2. Make the parser more error resistant so that you can avoid annoying your users if they type words your lexicon doesn't understand.
3. Improve the grammar by handling more things like numbers.
4. Think about how you might use this `Sentence` class in your game to do more fun things with a user's input.

## Common Student Questions

I can't seem to make `assert_raises` work right.

Make sure you are writing `assert_raises(exception, callable, parameters)` and *not* writing `assert_raises(exception, callable(parameters))`. Notice how the second form is calling the function then passing the result to `assert_raises` which is *wrong*. You have to pass the function to call *and* its arguments to `assert_raises` instead.

# Exercise 50: Your First Website

These final three exercises will be very hard and you should take your time with them. In this first one you'll build a simple web version of one of your games. Before you attempt this exercise you *must* have completed Exercise 46 successfully and have a working `pip` installed such that you can install packages and know how to make a skeleton project directory. If you don't remember how to do this, go back to Exercise 46 and do it all over again.

## Installing `lpthw.web`

Before creating your first web application, you'll first need to install the "web framework" called `lpthw.web`. The term "framework" generally means "some package that makes it easier for me to do something". In the world of web applications, people create "web frameworks" to compensate for the difficult problems they've encountered when making their own sites. They share these common solutions in the form of a package you can download to bootstrap your own projects.

In our case, we'll be using the `lpthw.web` framework, but there are many, many, *many* others you can choose from. For now, learn `lpthw.web` then branch out to another one when you're ready (or just keep using `lpthw.web` since it's good enough).

Using `pip` install `lpthw.web`:

```
$ sudo pip install lpthw.web
[sudo] password for zedshaw:
Downloading/unpacking lpthw.web
  Running setup.py egg_info for package lpthw.web

Installing collected packages: lpthw.web
  Running setup.py install for lpthw.web

Successfully installed lpthw.web
Cleaning up...
```

This will work on Linux and Mac OSX computers, but on Windows just drop the `sudo` part of the `pip` install command and it should work. If not, go back to Exercise 46 and make sure you can do it reliably.

### Warning

Other Python programmers will warn you that `lpthw.web` is just a fork of another web framework called `web.py`, and that `web.py` has too much "magic". If they say this, point out to them that Google App Engine originally used `web.py` and not a single Python programmer complained that it had too much magic, because they all worked at Google. If it's good enough for Google, then it's good enough for you to get started. Then, just get back to learning to code and ignore their goal of indoctrination over education.

# Make A Simple "Hello World" Project

Now you're going to make an initial very simple "Hello World" web application and project directory using `lpthw.web`. First, make your project directory:

```
$ cd projects
$ mkdir gothonweb
$ cd gothonweb
$ mkdir bin gothonweb tests docs templates
$ touch gothonweb/__init__.py
$ touch tests/__init__.py
```

You'll be taking the game from Exercise 42 and making it into a web application, so that's why you're calling it `gothonweb`. Before you do that, we need to create the most basic `lpthw.web` application possible. Put the following code into `bin/app.py`:

```
import web

urls = (
    '/', 'index'
)

app = web.application(urls, globals())

class index:
    def GET(self):
        greeting = "Hello World"
        return greeting

if __name__ == "__main__":
    app.run()
```

Then run the application like this:

```
$ python bin/app.py
http://0.0.0.0:8080/
```

However, if you did this:

```
$ cd bin/ # WRONG! WRONG! WRONG!
$ python app.py # WRONG! WRONG! WRONG!
```

Then you are doing it *wrong*. In all python projects you do not `cd` into a lower directory to run things. You stay at the top and run everything from there so that all of the system can access all the modules and files. Go reread Exercise 46 to understand a project layout and how to use it if you did this.

Finally, use your web browser and go to the URL `http://localhost:8080/` and you should see two things. First, in your browser you'll see `Hello, world!`. Second, you'll see your terminal with new output like this:

```
$ python bin/app.py
http://0.0.0.0:8080/
127.0.0.1:59542 - - [13/Jun/2011 11:44:43] "HTTP/1.1 GET /" - 200 OK
127.0.0.1:59542 - - [13/Jun/2011 11:44:43] "HTTP/1.1 GET /favicon.ico" - 404 Not Found
```

Those are log messages that `lpthw.web` prints out so you can see that the server is working, and what the browser is doing behind the scenes. The log messages help you debug and figure out when you have problems. For example, it's saying that your browser tried to get `/favicon.ico` but that file didn't exist so it returned `404 Not Found` status code.

I haven't explained the way *any* of this web stuff works yet, because I want to get you setup and ready to roll so that I can explain it better in the next two exercises. To accomplish this, I'll have you break your `lpthw.web` application in various ways and then restructure it so that you know how it's setup.

# What's Going On?

Here's what's happening when your browser hits your application:

1. Your browser makes a network connection to your own computer, which is called `localhost` and is a standard way of saying "whatever my own computer is called on the network". It also uses port `8080`.
2. Once it connects, it makes an HTTP request to the `bin/app.py` application and asks for the `/` URL, which is commonly the first URL on any website.
3. Inside `bin/app.py` you've got a list of URLs and what classes they match. The only one we have is the `'/'`, `'index'` mapping. This means that whenever someone goes to `/` with a browser, `lpthw.web` will find the `class index` and load it to handle the request.
4. Now that `lpthw.web` has found `class index` it calls the `index.GET` method on an instance of that class to actually handle the request. This function runs, and simply returns a string for what `lpthw.web` should send to the browser.
5. Finally, `lpthw.web` has handled the request and sends this response to the browser which is what you are seeing.

Make sure you really understand this. Draw up a diagram of how this information flows from your browser, to `lpthw.web`, then to `index.GET` and back to your browser.

# Fixing Errors

First, delete line 11 where you assign the `greeting` variable, then hit refresh in your browser. You should see an error

page now that gives you lots of information on how your application just exploded. You know that the variable `greeting` is now missing, but `lpthw.web` gives you this nice error page to track down exactly where. Do each of the following with this page:

1. Look at each of the `Local vars` outputs (click on them) and see if you can follow what variables it's talking about and where they are.
2. Look at the `Request Information` section and see if it matches anything you're already familiar with. This is information that your web browser is sending to your `gothonweb` application. You normally don't even know that it's sending this stuff, so now you get to see what it does.
3. Try breaking this simple application in other ways and explore what happens. Don't forget to also look at the logs being printed into your terminal as `lpthw.web` will put other stack traces and information there too.

# Create Basic Templates

You can break your `lpthw.web` application, but did you notice that "Hello World" isn't a very good HTML page? This is a web application, and as such it needs a proper HTML response. To do that you will create a simple template that says "Hello World" in a big green font.

The first step is to create a `templates/index.html` file that looks like this:

```
$def with (greeting)

<html>
  <head>
    <title>Gothons Of Planet Percal #25</title>
  </head>
  <body>

    $if greeting:
      I just wanted to say <em style="color: green; font-size: 2em;">$greeting</em>.
    $else:
      <em>Hello</em>, world!

  </body>
</html>
```

If you know what HTML is then this should look fairly familiar. If not, research HTML and try writing a few web pages by hand so you know how it works. This HTML file however is a *template*, which means that `lpthw.web` will fill in "holes" in the text depending on variables you pass in to the template. Every place you see `$greeting` will be a variable you'll pass to the template that alters its contents.

To make your `bin/app.py` do this, you need to add some code to tell `lpthw.web` where to load the template and to render it. Take that file and change it like this:

```
import web

urls = (
    '/', 'Index'
)

app = web.application(urls, globals())
```

```
render = web.template.render('templates/')

class Index(object):
    def GET(self):
        greeting = "Hello World"
        return render.index(greeting = greeting)

if __name__ == "__main__":
    app.run()
```

Pay close attention to the new `render` variable, and how I changed the last line of `index.GET` so it returns `render.index()` passing in your `greeting` variable.

Once you have that in place, reload the web page in your browser and you should see a different message in green. You should also be able to do a `View Source` on the page in your browser to see that it is valid HTML.

This may have flown by you very fast, so let me explain how a template works:

1. In your `bin/app.py` you've added a new variable `render` which is a `web.template.render` object.
2. This `render` object knows how to load `.html` files out of the `templates/` directory because you passed that to it as a parameter.
3. Later in your code, when the browser hits the `index.GET` like before, instead of just returning the string `greeting`, you call `render.index` and pass the `greeting` to it as a variable.
4. This `render.index` method is kind of a *magic* function where the `render` object sees that you're asking for `index`, goes into the `templates/` directory, looks for a page named `index.html`, and then "renders" it, or converts it.
5. In the `templates/index.html` file you see the beginning definition that says this template takes a `greeting` parameter, just like a function. Also, just like Python this template is indentation sensitive, so make sure you get them right.
6. Finally, you have the HTML in `templates/index.html` that looks at the `greeting` variable, and if it's there, prints one message using the `$greeting`, or a default message.

To get deeper into this, change the `greeting` variable and the HTML to see what effect it has. Also create another template named `templates/foo.html` and render that using `render.foo()` instead of `render.index()` like before. This will show you how the name of the function you call on `render` is just matched to a `.html` file in `templates/`.

# Study Drills

1. Read the documentation at <http://webpy.org/> which is the same as the `lpthw.web` project.
2. Experiment with everything you can find there, including their example code.
3. Read about HTML5 and CSS3 and make some other `.html` and `.css` files for practice.
4. If you have a friend who knows Django and is willing to help you, then consider doing Ex 50, 51, and 52 in Django instead to see what that's like.

# Common Student Questions

I can't seem to connect to `http://localhost:8080/`.

Try going to `http://127.0.0.1:8080/` instead.

What is the difference between `lpthw.web` and `web.py`?

No difference. I simply "locked" `web.py` at a particular version so that it would be consistent for students, then named it `lpthw.web`. Later versions of `web.py` might be different from this version.

I can't find `index.html` (or just about anything).

You probably are doing `cd bin/` first and then trying to work with the project. Do not do this. All of the commands and instructions assume you are one directory above `bin/`, so if you can't type `python bin/app.py` then you are in the wrong directory.

Why do we assign `greeting=greeting` when we call the template?

You are not assigning to `greeting` you are setting a named parameter to give to the template. It's sort of an assignment, but it only affects the call to the template function.

I can't use port 8080 on my computer.

You probably have an anti-virus program installed that is using that port. Try a different port.

After installing `lpthw.web` I get `ImportError "No module named web"`.

You most likely have multiple versions of Python installed and are using the wrong one, or you didn't do the install correctly because of an old version of `pip`. Try uninstalling `lpthw.web` and reinstalling it. If that doesn't work make triple sure you're using the right version of Python.

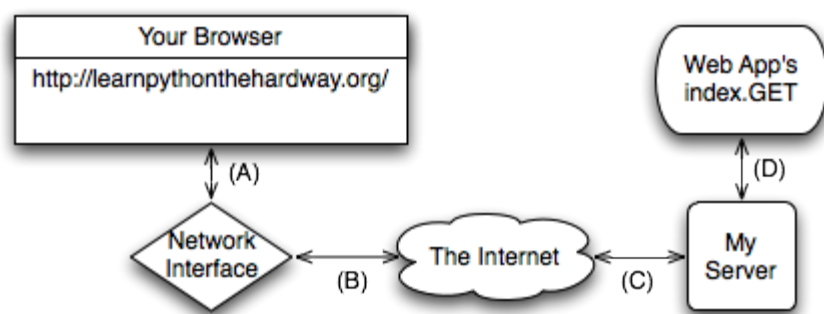

# Exercise 51: Getting Input From A Browser

While it's exciting to see the browser display "Hello World", it's even more exciting to let the user submit text to your application from a form. In this exercise we'll improve our starter web application using forms and storing information about the user into their "session".

## How The Web Works

Time for some boring stuff. You need to understand a bit more about how the web works before you can make a form. This description isn't complete, but it's accurate and will help you figure out what might be going wrong with your application. Also, creating forms will be easier if you know what they do.

I'll start with a simple diagram that shows you the different parts of a web request and how the information flows:

I've labeled the lines with letters so I can walk you through a regular request process:

1. You type in the url `http://learnpythonthehardway.org/` into your browser and it sends the request out on line (A) to your computer's network interface.
2. Your request goes out over the internet on line (B) and then to the remote computer on line (C) where my server accepts the request.
3. Once my computer accepts it, my web application gets it on line (D), and my Python code runs the `index.GET` handler.
4. The response comes out of my Python server when I `return` it, and goes back to your browser over line (D) again.
5. The server running this site takes the response off line (D) then sends it back over the internet on line (C).
6. The response from the server then comes off the internet on line (B), and your computer's network interface

hands it to your browser on `line (A)`.

7. Finally, your browser then displays the response.

In this description there are a few terms you should know so that you have a common vocabulary to work with when talking about your web application:

## Browser

The software that you're probably using every day. Most people don't know what it really does, they just call it "the internet". Its job is to take addresses (like <http://learnpythonthehardway.org>) you type into the URL bar, then use that information to make requests to the server at that address.

## Address

This is normally a URL (Uniform Resource Locator) like <http://learnpythonthehardway.org/> and indicates where a browser should go. The first part `http` indicates the protocol you want to use, in this case "Hyper-Text Transport Protocol". You can also try <ftp://ibiblio.org/> to see how "File Transport Protocol" works. The `learnpythonthehardway.org` part is the "hostname", or a human readable address you can remember and which maps to a number called an IP address, similar to a telephone number for a computer on the Internet. Finally, URLs can have a trailing `path` like the `/book/` part of <http://learnpythonthehardway.org/book/> which indicates a file or some resource *on the server* to retrieve with a request. There are many other parts, but those are the main ones.

## Connection

Once a browser knows what protocol you want to use (`http`), what server you want to talk to ([learnpythonthehardway.org](http://learnpythonthehardway.org)), and what resource on that server to get, it must make a connection. The browser simply asks your Operating System (OS) to open a "port" to the computer, usually port 80. When it works the OS hands back to your program something that works like a file, but is actually sending and receiving bytes over the network wires between your computer and the other computer at "[learnpythonthehardway.org](http://learnpythonthehardway.org)". This is also the same thing that happens with <http://localhost:8080/> but in this case you're telling the browser to connect to your own computer (`localhost`) and use port 8080 rather than the default of 80. You could also do <http://learnpythonthehardway.org:80/> and get the same result, except you're explicitly saying to use port 80 instead of letting it be that by default.

## Request

Your browser is connected using the address you gave. Now it needs to ask for the resource it wants (or you want) on the remote server. If you gave `/book/` at the end of the URL, then you want the file (resource) at `/book/`, and most servers will use the real file `/book/index.html` but pretend it doesn't exist. What the browser does to get this resource is send a *request* to the server. I won't get into exactly how it does this, but just understand that it has to send something to query the server for the request. The interesting thing is that these "resources" don't have to be files. For instance, when the browser in your application asks for something, the server is returning something your Python code generated.

## Server

The server is the computer at the end of a browser's connection that knows how to answer your browser's requests for files/resources. Most web servers just send files, and that's actually the majority of traffic. But you're actually building a server in Python that knows how to take requests for resources, and then return strings that you craft using Python. When you do this crafting, *you* are pretending to be a file to the browser, but really it's just code. As you can see from Ex. 50, it also doesn't take much code to create a response.

## Response

This is the HTML (css, javascript, or images) your server wants to send back to the browser as the answer to the browser's request. In the case of files, it just reads them off the disk and sends them to the browser, but it wraps the contents of the disk in a special "header" so the browser knows what it's getting. In the case of your application, you're still sending the same thing, including the header, but you generate that data on the fly with your Python code.

That is the fastest crash course in how a web browser accesses information on servers on the internet. It should work well enough for you to understand this exercise, but if not, read about it as much as you can until you get it. A really good way to do that is to take the diagram, and break different parts of the web application you did in Exercise 50. If you can break your web application in predictable ways using the diagram, you'll start to understand how it works.

# How Forms Work

The best way to play with forms is to write some code that accepts form data, and then see what you can do. Take your `bin/app.py` file and make it look like this:

```
import web

urls = (
    '/hello', 'Index'
)

app = web.application(urls, globals())

render = web.template.render('templates/')

class Index(object):
    def GET(self):
        form = web.input(name="Nobody")
        greeting = "Hello, %s" % form.name

        return render.index(greeting = greeting)

if __name__ == "__main__":
    app.run()
```

Restart it (hit CTRL-c and then run it again) to make sure it loads again, then with your browser go to `http://localhost:8080/hello` which should display, "I just wanted to say Hello, Nobody." Next, change the URL in your browser to `http://localhost:8080/hello?name=Frank` and you'll see it say "Hello, Frank." Finally, change the `name=Frank` part to be your name. Now it's saying hello to you.

Let's break down the changes I made to your script.

1. Instead of just a string for `greeting` I'm now using `web.input` to get data from the browser. This function takes a key=value set of defaults, parses the `?name=Frank` part of the URL you give it, and then returns a nice object for you to work with that represents those values.
2. I then construct the `greeting` from the new `form.name` attribute of the `form` object, which should be very familiar to you by now.
3. Everything else about the file is the same as before.

You're also not restricted to just one parameter on the URL. Change this example to give two variables like this:

`http://localhost:8080/hello?name=Frank&greet=Hola`. Then change the code to get `form.name` and `form.greet` like this:

```
greeting = "%s, %s" % (form.greet, form.name)
```

After that, try the URL. Next, leave out the `&greet=Hola` part so that you can see the error you get. Since `greet` doesn't have a default value in `web.input(name="Nobody")` then it is a required field. Now go back and make it have a default in the `web.input` call to see how you fix this. Another thing you can do is set its default to `greet=None` so that you can check if it exists and then give a better error message, like this:

```
form = web.input(name="Nobody", greet=None)

if form.greet:
    greeting = "%s, %s" % (form.greet, form.name)
    return render.index(greeting = greeting)
else:
    return "ERROR: greet is required."
```

# Creating HTML Forms

Passing the parameters on the URL works, but it's kind of ugly and not easy to use for regular people. What you really want is a "POST form", which is a special HTML file that has a `<form>` tag in it. This form will collect information from the user, then send it to your web application just like you did above.

Let's make a quick one so you can see how it works. Here's the new HTML file you need to create, in `templates/hello_form.html`:

```
<html>
  <head>
    <title>Sample Web Form</title>
  </head>
</body>

<h1>Fill Out This Form</h1>

<form action="/hello" method="POST">
  A Greeting: <input type="text" name="greet">
  <br/>
  Your Name: <input type="text" name="name">
  <br/>
  <input type="submit">
</form>

</body>
</html>
```

You should then change `bin/app.py` to look like this:

```
import web

urls = (
```

```

    '/hello', 'Index'
)

app = web.application(urls, globals())

render = web.template.render('templates/')

class Index(object):
    def GET(self):
        return render.hello_form()

    def POST(self):
        form = web.input(name="Nobody", greet="Hello")
        greeting = "%s, %s" % (form.greet, form.name)
        return render.index(greeting = greeting)

if __name__ == "__main__":
    app.run()

```

Once you've got those written up, simply restart the web application again and hit it with your browser like before.

This time you'll get a form asking you for "A Greeting" and "Your Name". When you hit the `Submit` button on the form, it will give you the same greeting you normally get, but this time look at the URL in your browser. See how it's `http://localhost:8080/hello` even though you sent in parameters.

The part of the `hello_form.html` file that makes this work is the line with `<form action="/hello" method="POST">`. This tells your browser to:

1. Collect data from the user using the form fields inside the form.
2. Send them to the server using a `POST` type of request, which is just another browser request that "hides" the form fields.
3. Send that to the `/hello` URL (as shown in the `action="/hello"` part).

You can then see how the two `<input>` tags match the names of the variables in your new code. Also notice that instead of just a `GET` method inside `class index`, I have another method `POST`.

How this new application works is:

1. The browser first hits the web application at `/hello` but it sends a `GET`, so our `index.GET` function runs and returns the `hello_form`.
2. You fill out the form in the browser, and the browser does what the `<form>` says and sends the data as a `POST`.
3. The web application then runs the `index.POST` method rather than the `index.GET` method to handle this request.
4. This `index.POST` method then does what it normally does to send back the hello page like before. There's really nothing new in here, it's just moved into a new function.

As an exercise, go into the `templates/index.html` file and add a link *back* to just `/hello` so that you can keep filling out the form and seeing the results. Make sure you can explain how this link works and how it's letting you cycle between `templates/index.html` and `templates/hello_form.html` and what's being run inside this latest Python code.

# Creating A Layout Template

When you work on your game in the next Exercise, you'll need to make a bunch of little HTML pages. Writing a full web page each time will quickly become tedious. Luckily you can create a "layout" template, or a kind of shell that will wrap all your other pages with common headers and footers. Good programmers try to reduce repetition, so layouts are essential for being a good programmer.

Change `templates/index.html` to be like this:

```
$def with (greeting)

$if greeting:
    I just wanted to say <em style="color: green; font-size: 2em;">$greeting</em>.
$else:
    <em>Hello</em>, world!
```

Then change `templates/hello_form.html` to be like this:

```
<h1>Fill Out This Form</h1>

<form action="/hello" method="POST">
    A Greeting: <input type="text" name="greet">
    <br/>
    Your Name: <input type="text" name="name">
    <br/>
    <input type="submit">
</form>
```

All we're doing is stripping out the "boilerplate" at the top and the bottom which is always on every page. We'll put that back into a single `templates/layout.html` file that handles it for us from now on.

Once you have those changes, create a `templates/layout.html` file with this in it:

```
$def with (content)

<html>
<head>
    <title>Gothons From Planet Percal #25</title>
</head>
<body>

$:content

</body>
</html>
```

This file looks like a regular template, except that it's going to be passed the *contents* of the other templates and used to *wrap* them. Anything you put in here doesn't need to be in the other templates. You should also pay attention to how `$:content` is written, since it's a little different from the other template variables.

The *final* step is to change the line that makes the `render` object to be this:

```
render = web.template.render('templates/', base="layout")
```

Which tells `lpthw.web` to use the `templates/layout.html` file as the *base* template for all the other templates. Restart your application and then try to change the layout in interesting ways, but without changing the other templates.

# Writing Automated Tests For Forms

It's easy to test a web application with your browser by just hitting refresh, but come on, we're programmers here. Why do some repetitive task when we can write some code to test our application? What you're going to do next is write a little test for your web application form based on what you learned in Exercise 47. If you don't remember Exercise 47, read it again.

You need to do a bit of setup to make Python let you load your `bin/app.py` file for testing. When we get to Exercise 52 you'll change this, but for now create an empty `bin/__init__.py` file so Python thinks `bin/` is a directory.

I've also created a simple little function for `lpthw.web` that lets you assert things about your web application's response, aptly named `assert_response`. Create the file `tests/tools.py` with these contents:

```
from nose.tools import *
import re

def assert_response(resp, contains=None, matches=None, headers=None, status="200"):
    assert status in resp.status, "Expected response %r not in %r" % (status,
resp.status)

    if status == "200":
        assert resp.data, "Response data is empty."

    if contains:
        assert contains in resp.data, "Response does not contain %r" % contains

    if matches:
        reg = re.compile(matches)
        assert reg.matches(resp.data), "Response does not match %r" % matches

    if headers:
        assert_equal(resp.headers, headers)
```

Once that's in place you can write your automated test for the last version of the `bin/app.py` file you created. Create a new file named `tests/app_tests.py` with this:

```
from nose.tools import *
from bin.app import app
from tests.tools import assert_response

def test_index():
    # check that we get a 404 on the / URL
    resp = app.request("/")
    assert_response(resp, status="404")
```

```
# test our first GET request to /hello
resp = app.request("/hello")
assert_response(resp)

# make sure default values work for the form
resp = app.request("/hello", method="POST")
assert_response(resp, contains="Nobody")

# test that we get expected values
data = {'name': 'Zed', 'greet': 'Hola'}
resp = app.request("/hello", method="POST", data=data)
assert_response(resp, contains="Zed")
```

Finally, use nosetests to run this test setup and test your web application:

```
$ nosetests
.
-----
Ran 1 test in 0.059s

OK
```

What I'm doing here is I'm actually *importing* the whole application from the `bin/app.py` module, then running it manually. The `lpthw.web` framework has a very simple API for processing requests, which looks like this:

```
app.request(localpart='/', method='GET', data=None, host='0.0.0.0:8080',
            headers=None, https=False)
```

This means you can pass in the URL as the first parameter, then change the method of the request, as well as what form data you send, including the host and headers. This works without running an actual web server so you can do tests with automated tests and also use your browser to test a running server.

To validate responses from this function, use the `assert_response` function from `tests.tools` which has:

```
assert_response(resp, contains=None, matches=None, headers=None, status="200")
```

Pass in the response you get from calling `app.request` then add things you want checked. Use the `contains` parameter to make sure that the response contains certain values. Use the `status` parameter to check for certain responses. There's actually quite a lot of information in this little function so it would be good for you to study it.

In the `tests/app_tests.py` automated test I'm first making sure the `/` URL returns a "404 Not Found" response, since it actually doesn't exist. Then I'm checking that `/hello` works with both a `GET` and `POST` form. Following the test should be fairly simple, even if you might not totally know what's going on.

Take some time studying this latest application, especially how the automated testing works. Make sure you understand how I imported the application from `bin/app.py` and ran it directly for the automated test. This is an important trick that will lead to more learning.

# Study Drills

1. Read even more about HTML, and give the simple form a better layout. It helps to draw what you want to do on paper and *then* implement it with HTML.
2. This one is hard, but try to figure out how you'd do a file upload form so that you can upload an image and save it to the disk.
3. This is even more mind-numbing, but go find the HTTP RFC (which is the document that describes how HTTP works) and read as much of it as you can. It is really boring, but comes in handy once in a while.
4. This will also be really difficult, but see if you can find someone to help you setup a web server like Apache, Nginx, or thttpd. Try to serve a couple of your .html and .css files with it just to see if you can. Don't worry if you can't, web servers kind of suck.
5. Take a break after this and just try making as many different web applications as you can. You should *definitely* read about sessions in `web.py` (which is the same as `lpthw.web`) so you can understand how to keep state for a user.

# Common Student Questions

I get `ImportError "No module named bin.app"`.

Again, this is either because you are in the wrong directory, did not make a `bin/__init__.py` file, or did not set `PYTHONPATH=.` in your shell. Always remember these solutions as they are so incredibly common that running to ask why you're getting that error will only slow you down.

I get `__template__() takes no arguments (1 given)` when I run the template.

You probably forgot to put `$def with (greeting)` or a similar variable declaration at the top of the template.

# Exercise 52: The Start Of Your Web Game

We're coming to the end of the book, and in this exercise I'm going to really challenge you. When you're done, you'll be a reasonably competent Python beginner. You'll still need to go through a few more books and write a couple more projects, but you'll have the skills to complete them. The only thing in your way will be time, motivation, and resources.

In this exercise, we won't make a complete game, but instead we'll make an "engine" that can run the game from Exercise 42 in the browser. This will involve `refactoring` Exercise 42, mixing in the structure from Exercise 47, adding automated tests, and finally creating a web engine that can run the games.

This exercise will be *huge*, and I predict you could spend anywhere from a week to months on it before moving on. It's best to attack it in little chunks and do a bit a night, taking your time to make everything work before moving on.

## Refactoring The Exercise 42 Game

You've been altering the `gothonweb` project for two exercises and you'll do it one more time in this exercise. The skill you're learning is called "refactoring", or as I like to call it, "fixing stuff". Refactoring is a term programmers use to describe the process of taking old code, and changing it to have new features or just to clean it up. You've been doing this without even knowing it, as it's second nature to building software.

What you'll do in this part is take the ideas from Exercise 47 of a testable "map" of Rooms, and the game from Exercise 42, and combine them together to create a new game structure. It will have the same content, just "refactored" to have a better structure.

First step is to grab the code from `ex47/game.py` and copy it to `gothonweb/map.py` and copy `tests/ex47_tests.py` file to `tests/map_tests.py` and run `nosetests` again to make sure it keeps working.

### Note

From now on I won't show you the output of a test run, just assume that you should be doing it and it'll look like the above unless you have an error.

Once you have the code from Exercise 47 copied over, it's time to refactor it to have the Exercise 42 map in it. I'm going to start off by laying down the basic structure, and then you'll have an assignment to make the `map.py` file and the `map_tests.py` file complete.

First thing to do is lay out the basic structure of the map using the `Room` class as it is now:

```
class Room(object):

    def __init__(self, name, description):
        self.name = name
        self.description = description
        self.paths = {}

    def go(self, direction):
        return self.paths.get(direction, None)

    def add_paths(self, paths):
        self.paths.update(paths)

central_corridor = Room("Central Corridor",
    """
    The Gothons of Planet Percal #25 have invaded your ship and destroyed
    your entire crew. You are the last surviving member and your last
    mission is to get the neutron destruct bomb from the Weapons Armory,
    put it in the bridge, and blow the ship up after getting into an
    escape pod.

    You're running down the central corridor to the Weapons Armory when
    a Gothon jumps out, red scaly skin, dark grimy teeth, and evil clown costume
    flowing around his hate filled body. He's blocking the door to the
    Armory and about to pull a weapon to blast you.
    """)

laser_weapon_armory = Room("Laser Weapon Armory",
    """
    Lucky for you they made you learn Gothon insults in the academy.
    You tell the one Gothon joke you know:
    Lbhe zbgure vf fb sng, jura fur fvgf nebhaq gur ubhfr, fur fvgf nebhaq gur ubhfr.
    The Gothon stops, tries not to laugh, then busts out laughing and can't move.
    While he's laughing you run up and shoot him square in the head
    putting him down, then jump through the Weapon Armory door.

    You do a dive roll into the Weapon Armory, crouch and scan the room
    for more Gothons that might be hiding. It's dead quiet, too quiet.
    You stand up and run to the far side of the room and find the
    neutron bomb in its container. There's a keypad lock on the box
    and you need the code to get the bomb out. If you get the code
    wrong 10 times then the lock closes forever and you can't
    get the bomb. The code is 3 digits.
    """)

the_bridge = Room("The Bridge",
    """
    The container clicks open and the seal breaks, letting gas out.
    You grab the neutron bomb and run as fast as you can to the
    bridge where you must place it in the right spot.

    You burst onto the Bridge with the netron destruct bomb
    under your arm and surprise 5 Gothons who are trying to
    take control of the ship. Each of them has an even uglier
    clown costume than the last. They haven't pulled their
    weapons out yet, as they see the active bomb under your
    arm and don't want to set it off.
    """)
```

```

""" )

escape_pod = Room("Escape Pod",
"""
You point your blaster at the bomb under your arm
and the Gothons put their hands up and start to sweat.
You inch backward to the door, open it, and then carefully
place the bomb on the floor, pointing your blaster at it.
You then jump back through the door, punch the close button
and blast the lock so the Gothons can't get out.
Now that the bomb is placed you run to the escape pod to
get off this tin can.

You rush through the ship desperately trying to make it to
the escape pod before the whole ship explodes. It seems like
hardly any Gothons are on the ship, so your run is clear of
interference. You get to the chamber with the escape pods, and
now need to pick one to take. Some of them could be damaged
but you don't have time to look. There's 5 pods, which one
do you take?
""" )

the_end_winner = Room("The End",
"""
You jump into pod 2 and hit the eject button.
The pod easily slides out into space heading to
the planet below. As it flies to the planet, you look
back and see your ship implode then explode like a
bright star, taking out the Gothon ship at the same
time. You won!
""" )

the_end_loser = Room("The End",
"""
You jump into a random pod and hit the eject button.
The pod escapes out into the void of space, then
implodes as the hull ruptures, crushing your body
into jam jelly.
"""
)

escape_pod.add_paths({
    '2': the_end_winner,
    '*': the_end_loser
})

generic_death = Room("death", "You died.")

the_bridge.add_paths({
    'throw the bomb': generic_death,
    'slowly place the bomb': escape_pod
})

laser_weapon_armory.add_paths({
    '0132': the_bridge,
    '*': generic_death
})

central_corridor.add_paths({
    'shoot!': generic_death,
    'dodge!': generic_death,
    'tell a joke': laser_weapon_armory
})

START = central_corridor

```

You'll notice that there are a couple of problems with our `Room` class and this map:

1. We have to put the text that was in the `if-else` clauses that got printed *before* entering a room as part of each room. This means you can't shuffle the map around which would be nice. You'll be fixing that up in this exercise.
2. There are parts in the original game where we ran code that determined things like the bomb's keypad code, or the right pod. In this game we just pick some defaults and go with it, but later you'll be given extra credit to make this work again.
3. I've just made a `generic_death` ending for all of the bad decisions, which you'll have to finish for me. You'll need to go back through and add in all the original endings and make sure they work.
4. I've got a new kind of transition labeled `"*"` that will be used for a "catch-all" action in the engine.

Once you've got that basically written out, here's the new automated test `tests/map_test.py` that you should have to get yourself started:

```
from nose.tools import *
from gothonweb.map import *

def test_room():
    gold = Room("GoldRoom",
                """This room has gold in it you can grab. There's a
                door to the north.""")
    assert_equal(gold.name, "GoldRoom")
    assert_equal(gold.paths, {})

def test_room_paths():
    center = Room("Center", "Test room in the center.")
    north = Room("North", "Test room in the north.")
    south = Room("South", "Test room in the south.")

    center.add_paths({'north': north, 'south': south})
    assert_equal(center.go('north'), north)
    assert_equal(center.go('south'), south)

def test_map():
    start = Room("Start", "You can go west and down a hole.")
    west = Room("Trees", "There are trees here, you can go east.")
    down = Room("Dungeon", "It's dark down here, you can go up.")

    start.add_paths({'west': west, 'down': down})
    west.add_paths({'east': start})
    down.add_paths({'up': start})

    assert_equal(start.go('west'), west)
    assert_equal(start.go('west').go('east'), start)
    assert_equal(start.go('down').go('up'), start)

def test_gothon_game_map():
    assert_equal(START.go('shoot!'), generic_death)
    assert_equal(START.go('dodge!'), generic_death)

    room = START.go('tell a joke')
    assert_equal(room, laser_weapon_armory)
```

Your task in this part of the exercise is to complete the map, and make the automated test completely validate the whole map. This includes fixing all the `generic_death` objects to be real endings. Make sure this works really well and that your test is as complete as possible because we'll be changing this map later and you'll use the tests to make sure it keeps working.

# Sessions And Tracking Users

At a certain point in your web application you'll need to keep track of some information and associate it with the user's browser. The web (because of HTTP) is what we like to call "stateless", which means each request you make is independent of any other requests being made. If you request page A, put in some data, and click a link to page B, all the data you sent to page A just disappears.

The solution to this is to create a little data store (usually in a database or on the disk) that uses a number unique to each browser to keep track of what that browser was doing. In the little `lpthw.web` framework it's fairly easy, and there's an example showing how it's done:

```
import web

web.config.debug = False

urls = (
    "/count", "count",
    "/reset", "reset"
)
app = web.application(urls, locals())
store = web.session.DiskStore('sessions')
session = web.session.Session(app, store, initializer={'count': 0})

class count:
    def GET(self):
        session.count += 1
        return str(session.count)

class reset:
    def GET(self):
        session.kill()
        return ""

if __name__ == "__main__":
    app.run()
```

To make this work, you need to create a `sessions/` directory where the application can put session storage. Do that, run this application and go to `/count`. Hit refresh and watch the counter go up. Close the browser and it *forgets* who you are, which is what we want for the game. There's a way to make the browser remember forever, but that makes testing and development harder. If you then go to `/reset`, and back to `/count` you can see your counter reset because you've killed the session.

Take the time to understand this code so you can see how the session starts off with the `count` equal to 0. Also try looking at the files in `sessions/` to see if you can open them up. Here's a Python session where I open up one and decode it:

```
>>> import pickle
>>> import base64
>>> base64.b64decode(open("sessions/XXXXX").read())
'(\dp1\nS' count' \np2\nI1\nsS' ip' \np3\nV127.0.0.1\np4\nsS' session_id' \np5\nS' XXXX' \np6\ns.'
>>>
>>> x = base64.b64decode(open("sessions/XXXXX").read())
>>>
```

```
>>> pickle.loads(x)
{'count': 1, 'ip': u'127.0.0.1', 'session_id': 'XXXXX'}
```

The sessions are really just dictionaries that get written to disk using `pickle` and `base64` libraries. There are probably as many ways to store and manage sessions as there are web frameworks, so it's not too important to know how these work. It does help if you need to debug the session or potentially clean them out.

# Creating An Engine

You should have your game map working and a good unit test for it. I now want to make a simple little game engine that will run the rooms, collect input from the player, and keep track of where a play is in the game. We'll be using the sessions you just learned to make a simple game engine that will:

1. Start a new game for new users.
2. Present the room to the user.
3. Take input from the user.
4. Run their input through the game.
5. Display the results and keep going until they die.

To do this, you're going to take the trusty `bin/app.py` you've been hacking on and create a fully working, session based, game engine. The catch is I'm going to make a very simple one with *basic HTML* files, and it'll be up to you to complete it. Here's the base engine:

```
import web
from gothonweb import map

urls = (
    '/game', 'GameEngine',
    '/', 'Index',
)

app = web.application(urls, globals())

# little hack so that debug mode works with sessions
if web.config.get('_session') is None:
    store = web.session.DiskStore('sessions')
    session = web.session.Session(app, store,
                                  initializer={'room': None})
    web.config._session = session
else:
    session = web.config._session

render = web.template.render('templates/', base="layout")

class Index(object):
    def GET(self):
        # this is used to "setup" the session with starting values
        session.room = map.START
        web.seeother("/game")

class GameEngine(object):
    def GET(self):
        if session.room:
```

```

        return render.show_room(room=session.room)
    else:
        # why is there here? do you need it?
        return render.you_died()

def POST(self):
    form = web.input(action=None)

    # there is a bug here, can you fix it?
    if session.room and form.action:
        session.room = session.room.go(form.action)

    web.seeother("/game")

if __name__ == "__main__":
    app.run()
```

There are even more new things in this script, but amazingly it's an entire web based game engine in a small file. The biggest "hack" in the script are the lines that bring the sessions back, which is needed so that debug mode reloading works. Otherwise, each time you hit refresh the sessions will disappear and the game won't work.

Before you run `bin/app.py` you need to change your `PYTHONPATH` environment variable. Don't know what that is? I know, it's kind of dumb you have to learn what this is to run even basic Python programs, but that's how Python people like things.

In your terminal, type:

```
export PYTHONPATH=$PYTHONPATH:.
```

On Windows PowerShell do:

```
$env:PYTHONPATH = "$env:PYTHONPATH; ."
```

You should only have to do it once per shell session, but if you get an import error, then you probably need to do this or you did it wrong.

You should next delete `templates/hello_form.html` and `templates/index.html` and create the two templates mentioned in the above code. Here's a very simple `templates/show_room.html`:

```

$def with (room)

<h1> $room.name </h1>

<pre>
$room.description
</pre>

$if room.name == "death":
    <p><a href="/">Play Again?</a></p>
$else:
    <p>
        <form action="/game" method="POST">
            - <input type="text" name="action"> <input type="SUBMIT">
        </form>
    </p>
```

That is the template to show a room as you travel through the game. Next you need one to tell someone they died in the case that they got to the end of the map on accident, which is `templates/you_died.html`:

```
<h1>You Died!</h1>

<p>Looks like you bit the dust.</p>
<p><a href="/">Play Again</a></p>
```

With those in place, you should now be able to do the following:

1. Get the test `tests/app_tests.py` working again so that you are testing the game. You won't be able to do much more than a few clicks in the game because of sessions, but you should be able to do some basics.
2. Remove the `sessions/*` files and make sure you've started over.
3. Run the `python bin/app.py` script and test out the game.

You should be able to refresh and fix the game like normal, and work with the game HTML and engine until it does all the things you want it to do.

# Your Final Exam

Do you feel like this was a huge amount of information thrown at you all at once? Good, I want you to have something to tinker with while you build your skills. To complete this exercise, I'm going to give you a final set of exercises for you to complete on your own. You'll notice that what you've written so far isn't very well built, it is just a first version of the code. Your task now is to make the game more complete by doing these things:

1. Fix all the bugs I mention in the code, and any that I didn't mention. If you find new bugs, let me know.
2. Improve all of the automated tests so that you test more of the application and get to a point where you use a test rather than your browser to check the application while you work.
3. Make the HTML look better.
4. Research logins and create a signup system for the application, so people can have logins and high scores.
5. Complete the game map, making it as large and feature complete as possible.
6. Give people a "help" system that lets them ask what they can do at each room in the game.
7. Add any other features you can think of to the game.
8. Create several "maps" and let people choose a game they want to run. Your `bin/app.py` engine should be able to run any map of rooms you give it, so you can support multiple games.
9. Finally, use what you learned in Exercises 48 and 49 to create a better input processor. You have most of the code necessary, you just need to improve the grammar and hook it up to your input form and the `GameEngine`.

Good luck!

# Common Student Questions

I'm using sessions in my game and I can't test it with nosetests.

You need to read about sessions in the reloader [http://webpy.org/cookbook/session\\_with\\_reloader](http://webpy.org/cookbook/session_with_reloader)

I get an **ImportError**.

Wrong directory. Wrong Python version. PYTHONPATH not set. No `__init__.py` file. Spelling mistake in import.

# Advice From An Old Programmer

You've finished this book and have decided to continue with programming. Maybe it will be a career for you, or maybe it will be a hobby. You'll need some advice to make sure you continue on the right path, and get the most enjoyment out of your newly chosen activity.

I've been programming for a very long time. So long that it's incredibly boring to me. At the time that I wrote this book, I knew about 20 programming languages and could learn new ones in about a day to a week depending on how weird they were. Eventually though this just became boring and couldn't hold my interest anymore. This doesn't mean I think programming *is* boring, or that *you* will think it's boring, only that *I* find it uninteresting at this point in my journey.

What I discovered after this journey of learning is that it's not the languages that matter but what you do with them. Actually, I always knew that, but I'd get distracted by the languages and forget it periodically. Now I never forget it, and neither should you.

Which programming language you learn and use doesn't matter. Do *not* get sucked into the religion surrounding programming languages as that will only blind you to their true purpose of being your tool for doing interesting things.

Programming as an intellectual activity is the *only* art form that allows you to create interactive art. You can create projects that other people can play with, and you can talk to them indirectly. No other art form is quite this interactive. Movies flow to the audience in one direction. Paintings do not move. Code goes both ways.

Programming as a profession is only moderately interesting. It can be a good job, but you could make about the same money and be happier running a fast food joint. You're much better off using code as your secret weapon in another profession.

People who can code in the world of technology companies are a dime a dozen and get no respect. People who can code in biology, medicine, government, sociology, physics, history, and mathematics are respected and can do amazing things to advance those disciplines.

Of course, all of this advice is pointless. If you liked learning to write software with this book, you should try to use it to improve your life any way you can. Go out and explore this weird wonderful new intellectual pursuit that barely anyone in the last 50 years has been able to explore. Might as well enjoy it while you can.

Finally, I'll say that learning to create software changes you and makes you different. Not better or worse, just different. You may find that people treat you harshly because you can create software, maybe using words like "nerd". Maybe

you'll find that because you can dissect their logic that they hate arguing with you. You may even find that simply knowing how a computer works makes you annoying and weird to them.

To this I have just one piece of advice: they can go to hell. The world needs more weird people who know how things work and who love to figure it all out. When they treat you like this, just remember that this is *your* journey, not theirs. Being different is not a crime, and people who tell you it is are just jealous that you've picked up a skill they never in their wildest dreams could acquire.

You can code. They cannot. That is pretty damn cool.

# Next Steps

You're not a programmer quite yet. I like to think of this book as giving you your "programming brown belt". You know enough to start another book on programming and handle it just fine. This book should have given you the mental tools and attitude you need to go through most Python books and actually learn something. It might even make it easy.

I recommend you check out some of these projects and try to build something with them:

- [The Django Tutorial](#) and try to build a web application with the [Django Web Framework](#).
- [SciPy](#) if you're into science, math, and engineering and also [Dexy](#) for when you want to write awesome papers that incorporate SciPy or any code really.
- [PyGame](#) and see if you can make a game with graphics and sound.
- [Pandas](#) for doing data manipulation and analysis.
- [Natural Language Tool Kit](#) for analyzing written text and writing things like spam filters and chat bots.
- [Requests](#) to learn the client side of HTTP and the web.
- [SimpleCV](#) to play with making your computer see things in the real world.
- [ScraPy](#) and try scraping some web sites to get information off them.
- [Panda3D](#) for doing 3D graphic and games.
- [Kivy](#) for doing user interfaces on desktops and mobile platforms.
- [SciKit-Learn](#) for machine learning applications.
- [Ren'Py](#) for doing interactive fiction games, similar to what you've built in this book but with pictures.
- [Learn C The Hard Way](#) after you're familiar with Python try learning C and algorithms with my other book. Take it slow, C is different but a very good thing to learn.

Pick one of the above projects, and go through any tutorials and documentation they have. As you go through it *type in all of the code* and make it work. That's how I do it, that's how every programmer does it. Reading programming documentation is not enough to learn it, you have to do it. After you get through the tutorial and any other documentation they have, make something. Anything will do, even something someone else has already written. Just make something.

Just understand anything you write will probably suck. That's alright though, I suck at every programming language I first start using. Nobody writes pure perfect gold when they're a beginner, and anyone who tells you they did is a huge liar.

Finally, remember that this is something you have to do at least a couple hours a night for a while before you can get good. If it helps, while you're struggling to learn Python every night, I'm hard at work learning to play guitar. I work at it about 2 or 4 hours a day and still practice scales.

Everyone is a beginner at something.
